If you do not short the center conductor (on the DUT) to ground
immediately before connecting to the analyzer you risk discharging a
large "capacitor" directly into the instrument. If I am at an antenna
farm I am grounding all my test gear prior to putting it into service.
There is a Ground lug on the 259B right next to the SO239. They
provide a Type N adaptor with a new meter, too, BTW.

MFJ isn't the only ones that can suffer at the hands of others.

I was trying to locate some interference using a UHF Yagi and a Motorola R2018 service monitor. Do not key up a hand held in front of the antenna. At least Motorola anticipated that, and it took out the picofuse behind the antenna connector instead of the front end mixer.

Good point except that none of the 3 analyzers that failed were (allegedly) attached to equipment. They were attached to antennas. Antennas normally do not have BFC's (big fat capacitors) attached, but do build up static charges. With the humidity currently at 60% or more, I don't think that's likely. Also, any antenna design, that would fry an analyzer, might also fry a radio front end. It's possible, but unlikely.

>If I am at an antenna

I carry a neon lamp line tester in my tool box. It's useful for checking AC power, but also for detecting high voltages on antenna terminals. It's amazing what I find at broadcast sites.

The plot thickens. I checked the accuracy of the MFJ-269 and is was off on the real part of anything it was measuring about +10%. A good 50 ohm load would read about 56 ohms. It didn't take long to find the culprit. Instead of 51.1 ohms (1%), R88 showed 54 ohms, while R85 and R86 read 52 ohms (or there about within the limits of my cheapo ohms-guesser). It therefore seems possible that the owner had transmitted into the instrument (even though he denies it). That also might explain how 3 out of 4 diodes were found fused open. Most diodes I've seen end up shorted when the junction is punctured. I'll be replacing all the 51.1 ohm resistors.

Meanwhile, I added a grounded load cap, returned the instrument to its owner, extorted a free lunch, applied the requisite instrument safety lecture, and warned him of the accuracy problem. The dip in the VSWR curve is all he needs at this time, which is unaffected by bridge imbalance.

Well, do the math. The front end of the service monitor is 50 ohms.
The fuse is probably 0.1A. Power to blow the fuse is:
    P = I^2 * R = 0.1^2 * 50 = 0.5 watts = +27dBm
I'll guess a 10dBi yagi and a 3 watt (+35dBm) HT into a 0dBi rubber
ducky.

[Q]: How close to the antenna can you use the HT before you blow the
fuse?

Go thee unto:
<http://www.terabeam.com/support/calculations/som.php>
and inscribe the tx power (in dBm) and the antenna gains into the
boxes. Use 0dB for coax losses and 440MHz for the frequency. Don't
worry about RX sensitivity. Plug in different values of distance
(miles) until you get an RX signal level of +27dBm. I get:
   0.0003 miles = 1.6 ft

So, stay at least 1.6 ft away from your antenna and you won't blow the
fuse. Please change my guesswork to match reality and recalculate.

Drivel: Yes, I know we're close to the near field and the numbers
aren't very accurate.

>Jeff-1.0

Jeff 2.0 (the upgraded version).

I don't suppose the reference to a "picofuse" is literal to amperage (pA), but the introduction of a 0.1A fuse is equally a supposition (I suppose, because from my experience with precision power measurement equipment, they often used a commercially available, specialty fuse rated at 10mA - a Wollaston wire).

>Power to blow the fuse is:
>   P = I^2 * R = 0.1^2 * 50 = 0.5 watts = +27dBm
    P = I^2 * R = 0.01^2 * 50 = 0.005 watts

Getting too close (less than 5 to 10 wavelengths, and for "gain" antennas, 20 wavelengths or more) negates directivity.

>Go thee unto:
><http://www.terabeam.com/support/calculations/som.php>
...
> I get: 0.0003 miles = 1.6 ft

Which is extremely suspect.

>Drivel: Yes, I know we're close to the near field and the numbers

Actually, humidity doesn't affect the charging all that much. What humidity affects is the leakage current across dirty insulators. P-static is a nice example of static charging in rain at 100% humidity, for instance.

It's true that dry dust or blowing snow are more notorious for charging, but just the clear sky current could provide some charging.

Also, any antenna design, that

> possible, but unlikely.

I don't know about that. A LNA with a FET front end might be an example of a ESD sensitive thing, but for HF, where we're usually more concerned about instantaneous dynamic range and strong signal handling, a more robust front end is common. One of those +20dBm LO mixers, for instance, is going to be quite robust.

I can think of a lot of antennas that won't be too hard on a radio front end that would cook a delicate detector diode hooked directly up to the antenna.

There's a whole literature on making neon lamp blinkers with an antenna and a ground.

Why would anyone connect that antenna analyzer to a transmitter (unless
using the BNC?)

wrote:

>but just the clear sky current could provide some charging.

There is a earth-sky current in the femtoamperes per cm� that has a constant potential gradient on the order of 600V/m (or something like that). This current is the return path for all lightning strike charge transfers, world-wide.

Few dipoles are co-planar, parallel wrt ground.

>Actually, humidity doesn't affect the charging all that much. What
>humidity affects is the leakage current across dirty insulators.

Which could easily overwhelm this femtoampere charge where a gigaOhm leakage is trivial (zealous Hams using teflon technology?).

Actually measuring this current (ca 1970s) required using two polonium-210 coated probes (what are still available as static brushes for vinyl records) feeding FETs.

The following link:
http://www.angelfire.com/electronic/cwillis/rad/brush.html
illustrates what the brush is like, and its electrical attributes.
Another source, the manufacturer (which deeply hides the polonium
reference):
http://www.nrdstaticcontrol.com/doc/microbalance.pdf

People do odd things. Some times it is noobs, sometimes someone connects the wrong cable and for some weird reason keys the transmitter, sometimes it is someone just not thinking.

I've seen too much stuff to not believe really crazy things don't happen.

It is a good lesson, (be wary) and I think that MFJ makes another "analyzer", the 207, which will suit the average user just fine, as long as they are not needing V/UHF. It's cheap, simple, small, and I used one before I got into HF mobile. It doesn't show anything but SWR. Given that that is what most people are interested in, it suits well.

Then after a bit of reading, and talking they might start to look for the interesting details, and the instruments to measure those details.

Absolutely, if acquiring an MFJ259B or the like is a stimulus to learn more of impedance, transmission lines and antennas, that is great.

Owen

Good question. I asked the same question when we discovered that the radio clubs Kenwood something HF transceiver had most of the components in the receiver front end vaporized or incinerated after a contest weekend. My best guess(tm) is that someone plugged one of the tangled mess of coax cables lurking behind the bench, into a live transmitter, thinking it was an antenna cable. Few of cables are labeled. Of course, nobody will admit to doing it.

My guess(tm) is that something like that happened with the MFJ.

Incidentally, in the box with the MFJ-269 was an N-male to UHF-female adapter, which brings back the possibility of an ESD discharge when the center pin was connected first.

Well, an admission of guilt would certainly be handy. Before anything can be repaired, a suitable culprit must be found or assigned. Nothing can be repaired without first establishing the blame.

If the owner confesses to gross negligence, the repair can proceed normally. However, if he refuses to accept the blame, someone else must be found. That's often difficult as one should not blame the person doing the repairs. It is sometimes convenient to loan the instrument to a fellow ham, and then blame them for blowing it up. As a last resort, inflicting inquisition style torture on the owner will eventually extract a confession, although subsequently getting paid for the repair might be difficult.

Well, what I've noticed is that when the humidity is low, I throw
lightning bolts when I walk across the carpet or slide across the car
seat. When the humidity is higher, then I don't have those problems.
I don't know how this correlates to charge buildup on an antenna, but
my guess(tm) is that there would be some connection.

>> Also, any antenna design, that
>> would fry an analyzer, might also fry a radio front end. It's

>about instantaneous dynamic range and strong signal handling, a more
>robust front end is common. One of those +20dBm LO mixers, for
>instance, is going to be quite robust.

In a past life, I helped design a marine HF xceiver, which had a +7dBm
mixer (SBL-1) in the front end. Between the antenna and the mixer,
was a low pass filter with no capacitors to ground. There were a few
failures, most of which were due to nearby lightning hits. However
some of these failures were blamed on static buildup.

The higher level mixers will certainly survive a bigger blast through
the antenna. But that's because there's a torroidal isolation
transformer between the antenna and the diode ring. See typical
+23dBm mixer at:
<http://www.minicircuits.com/pdfs/RAY-1+.pdf>
Also note that the maximum RF power is 350mw, which is well within the
range of what can be delivered by a good solid ESD blast via the
antenna. I don't think it will fry the diodes, but might blow the
tiny wire used in the torroids into a fuse.

>I can think of a lot of antennas that won't be too hard on a radio front
>end that would cook a delicate detector diode hooked directly up to the
>antenna.

Ok. I'll admit that the MJF-269 diodes, which are directly connected
to the antenna terminal, are more easily fried than a receiver front
end, which has a mess of circuitry, and possibly an antenna coupler,
between the antenna and the front end.

>> I carry a neon lamp line tester in my tool box. It's useful for

These days, it's called "energy scavenging" or "RF energy harvesting".
<http://www.eweekeurope.co.uk/news/scavenging-free-green-power-from-radio-waves-35622>
I used to have a 4 watt fluorescent lamp on top of my mobile antenna
that flickered with the transmitted envelope.

Oh.. that's an easy mistake to make. Bunch of coax with connectors lying on the floor, hook up the wrong one. Hook a switch up incorrectly. Coax switch without enough isolation (100W transmitter with a 20dB isolation switch is a watt into the analyzer..)

Anyone who has never accidentally cooked a piece of test equipment just hasn't been working long enough.

a few pA/sq meter and a kV/meter field is how I always remember it (in
round numbers) It's small, that's true.

>
> Few dipoles are co-planar, parallel wrt ground.

Well..   Consider a 20 meter long wire hanging 10 meters above the
ground (half a 80m dipole) so now you're talking tens of pA, 100 Meg
isolation isn't hard to get with clean insulators.  That 20 m wire is
like a 850 pF capacitor.  If assume, say, 25 pA charging current, you
get a volt every 42 seconds.  After half an hour or so, you're up to 40
volts or so..

Granted it's not a lot of Joules.. (heck, probably not even a microjoule)..

So fair weather charging isn't likely to kill your MFJ..

Back to the dust/rain/induction charging, which can certainly get the
levels needed.

It has to do with the leakage currents discharging you when it's more
humid. Interestingly, humid air has a higher breakdown field than dry air.

And, you can take ESD hits that degrade, but don't destroy, the part.
I've got some LNAs in my desk drawer that appear to work just fine,
except the NF is a bit higher than it used to be.

I've observed clear-air charge on a TV antenna (about 30' above ground
level) which was sufficient to create a visible spark when I touched
the center connector of the coax to a grounded static-drain block.

No rain at the time, no appreciable amount of dust (SF Bay area)...
just clear air with a mild breeze.

#laughing out loud#

Geoff, you're one of only four people alive today (I think) who would
remember that particular incident.

Yeah, I was the guy hidden under the bed with the remote-control box
for the "voice operated" flippers.

Oh, no, by no means - that was just my *first* time.

As in your case, the fuses tend to save most of my VOM/DVM foulups these days. Reminds me, I've gotta go grab some 250 mA mini-fuses to fix one of my meters and restock my oops box.

To paraphrase Foghorn Leghorn, "Fortunately, I always keep a spare set of feathers in my locker, for just such an occasion."

Sitting on my messy workbench are two almost identical and unlabeled coax cables ending in N connectors with BNC adapters attached. One goes to a militarized dummy load and power guesser. The other goes to the output of my HP8656A signal generator. It took about 5 years, but I finally got them mixed up and plugged a transmitter into the generator. Fortunately, either the HP8656A apparently has some manner of idiot protection inside, or I was simply lucky, as it survived my stupidity.

I thought so. :-)

For those that weren't there (almost the entire world), Dave and I grew up in Philly and had mutual friends.

It must of been either the summer of '70 or '71, someone gave me a huge spool of teflon coated #20 copper wire (worth a fortune but we did not know that) and someone else gave me a working pinball machine.

They both ended up in another friend's bedroom and with a box, some switches

and push bottons, we ended up with the world's first and possibly only
voice accuated pinball machine.

The reality of it all was Dave was under a bed next to the machine, pushing
buttons and flipping switches.

I remember one "mark" who would not believe that it wasn't real, even when
we moved the bed, Dave popped out and showed him the box. :-)

Geoff.

Oh.. I don't know on the ones in the drawer that's what did it (because they still work, after a fashion), but on some other ones where we did failure analysis, you can see the damage on the SEM photos.

We've got whole books full of pictures of this kind of thing.

That's partly why industry has gone from marking just sensitive things to marking everything ESD, including nuts and bolts. It's just too easy to get damage without any obvious signs. Consistent practices reduce the possibility, which increases yield. The concern is the "weakening" or "partial damage without causing outright failure" kind of scenario, especially in a hi-rel situation.

There's a lot of interest in figuring out a way to test for this kind of thing, as you can imagine.

And there's even evidence that the damage can heal (anneal), much like radiation damage (both are basically deposition of energy in the wrong place and the wrong time, right), but the mechanics of the process is poorly understood.

There could actually be a fair amount of particulates without you being aware of it. I used to work for a company that made things that created fine particles in air and we tried to remove the particles as well (often using electrostatic techniques).

For very small particles, they don't scatter the light very well so you don't see them. Ultimately, you get small enough: molecule sized and you get blue sky, but even fairly large particles (on the order of a wavelength of light in size) are basically invisible as such, but do increase the attenuation, and do scatter some light so you get decreasing visual contrast at long distances (called atmospheric perspective in the computer graphics biz) One way that cinematographers can make a room seem bigger is by putting a very small amount of haze into the room, because that makes distant things less contrasty, which your brain turns into "farther away".

Some numbers:

At 1 mg/cubic meter of 1 micron diameter particles, you won't see any noticeable haziness. That's about 2E15 particles per cubic meter, and each one can have a max charge of about 1E-13 coulomb. So you can potentially move 200 coulombs with a cubic meter of air. That gentle zephyr blowing by at 1 m/sec can move a lot of cubic meters in a fairly short time. Say you have a 1cm diameter antenna element.. it will intercept 0.01 cubic meters/sec of that breeze.. 2 Coulombs/sec -> 2 Amperes...

In reality, of course, the particles won't have that much charge (they'll repel each other, for one thing), and not all of the particles will touch your antenna, especially once it starts to charge, and so forth. When I was working with a Vollrath Electrostatic Charging scheme (like a Van de Graaff generator using dust instead of a belt) the best kind of charging current I got was 10-100 microamps with dust flowing in a 4" diameter pipe at several meters/sec.

But, the real thing is that you can get particulate charging in what seems to be perfectly clear air.

Compressed air system run into this kind of thing... you can have fine oil particles from the compressor, or condensed water particles from a sudden expansion of the compressed air, both of which might be invisible, but which can build up a surprising charge.

I thought HRD only controlled certain radios that actually had to be connected
to the host computer via a series or USB port? Or is the ability to go to other
web sites and stream audio from them some undocumented feature I missed? I'll
have to check that out? Thanks.

Yeah.. the guy or gal who figures out a good non-destructive, no
disassembly required way to detect latent ESD damage is going to be a
hero for those of us building one-off high-rel gear.  There have been
some partial solutions for specific parts, but no generalized way, yet.

That's easy. Because there's no emission designator for FCC approved
TDMA mobile/HT for ham radio. The ARRL is working on the problem.
<http://www.arrl.org/news/arrl-files-em-petition-em-em-request-for-temporary-waiver-em-with-fcc-regarding-vhf-voice-and-data-e>
Multiple time slot systems, such as DStar are currently approved. This
is nothing new. Just approval for P25 radios.

>You could build a very nice full duplex repeater on a single
>frequency that way.

Yes, except that the ARRL has decided to only petition for a waver for
single time slot TDMA, which can't be used for a repeater.

You're scheme would certainly work, and I too am wondering why nobody
has bothered to do it. Possibly because nobody really wants full
duplex (with echo, reverb, feedback, etc).

>Sure it's totally incompatible with current FM
>repeaters, but then, D-star isn't totally compatible either. D-star and

Dstar duz 5 independent simultaneous conversations through the
repeater. That's not what I would call a half measure.

>No filtering, much less intermod issues in multi station at onee site
>systems... all kinds of good comes of it.

Yep.

>Digital schemes on HF to replace SSB I can see having real trouble (the
>biggest is the lack of a "party line" capability, the other is the long
>propagation delay on HF paths), but on VHF and up FM, you already have a
>"one person talks at a time" by virtue of the standard FM demodulator.

Yep. We did that with Amtor (Sitor) for data. The big problem was getting the switching time between T/R to less than the prop delay. If you increase the time slicing to where it could handle voice (about 200Hz) but not be audible, the occupied bandwidth increases unacceptably wide for HF. It's possible to decrease the switching time, but then the latency (delay) increases to unacceptable levels. I don't think anyone really wants a repeater with a 1 second audio delay (even though they exist).

While not adding to your solution I saw this posting and had to put in
a plug for my simplification.

I made a simplification to Joe's beam and want to let others know.

  Instead of paying for those hose clamps, I simply use a short piece
of the tubing to hold the tape.  It takes a little Dremel grinding to
remove the step inside, but makes a nice, clean design with the hair-
pin match inside.

Matching, perhaps not so much, HOWEVER, the antenna pattern/phase/characteristics are *THE* most important aspect of a DF antenna/system. The DF antenna characteristics must be as close to ideal as possible. I've been involved in DF since my stint in the Navy and they went to great lengths to get the antenna sites ideal, for that reason.
Also...

But why I re-posted.... Thanks to Richard's post...
I forgot to mention a bead choke that I used with success on one of these beams.
They also significantly improved the performance of a four dipole Doppler type DF antenna
that one of the locals had and knew it was not right, but couldn't decide what to do to fix it..

We used two cores on the coax to get well above the coax 50 ohms.

The following cores will fit inside the PVC pipe and around RG-58 size coax.

Mouser: 623-2643540002
Fair-Rite (Mfr) # 2643540002
O.D. 0.562"
I.D. 0.25"
Len. 1.125
250 ohms @ 100MHz. [specs. I did not measure them as I recall]
171 ohms @ 25 MHz.

Finally,

Helmut,
  You have quite a bit of reading there with that sliding element.
Can't wait to dig into it.

73, Steve, K9DCI   Haven't read this group in ages.

Uhhh. It's been a long time since I worked on such a system (1975 I
think),
but IIR the prop delay through space for moderate distances kills the
idea.
Rough calculations gives a round trip delay, at 10 miles from the
repeater,
of about 0.1 ms. For two stations at that distance that's 0.1 ms not
available for sampling, bit width and processing. Keeping the BW down
also needs
rise and fall time as well as guard times. It added up quiclky back
then.
The vocoder becomes very important to reduce the data rate.

Hope I got that right...

I wonder whether you may not also have to be really careful with your
transceiver/receiver switching design. You'll really need to be able
to trust (and drive) those PIN diodes properly... goof up on even a
single time-slice and you could put enough TX power into your receiver
to turn its front end into a pile of smouldering char in a millisecond.

This isn't a problem with normal split-frequency repeaters, thanks to
the isolation in the duplexer cans.

Do any of the commercial TDMA systems use the same frequencies for
base->mobile and mobile->base? My recollection is that TDMA cellphone
systems operate with split uplink/downlink frequencies.

>>No filtering, much less intermod issues in multi station at onee site

>
>Yep.

But "no filtering" comes with its own set of concerns.

That was 1975. The only people who ever were exposed to any propigation delay where those rich enough to make a long distance call that was routed over satellite. If I remember correctly it was about $5 a minute to call New York from L.A.

This is 2011, everyone is used the the propigation delay of digital telephones, and VoIP. 150ms is tollerable.

Geoff.

Looks good.

I always wonder from where you people get the PVC tubes.
My local construction markets don't.

Since you have it, can you try to make the center elements movable,
this should work with the PVC tubes also.

w.

For you, perhaps. I have a mild learning disability and I can't use the
phone if there's too much hesi............tation. I have a twisted pair
that connects directly to an EOC at the push of a button. SMS works
great for me.

What's really funny is "music on hold" via mobile voice circuit.

I remember frying a scope once measuring audio from a distant studio
that was on the opposite mains leg. It was a 50 cents a pound government
surplus scope, not my 465.

I would never leave an unterminated transmission line connected to my
transmitter. You always want 50 Ohms on that line when connected to
your XMTR.

I also would never "guess", (which is a kind of "assume"), unless I
really had to. I know I learned this the hard way.

I am trying to use HFTA (from the 20th Edition Antenna Book) and am a little confused in the MicroDEM stage. I downloaded two DEM.gz files and placed them in C:\mapdata\DEMs\xxxxx.gz and yyyyy.gz. (I need two files because I am located near a boundary.) Should these gz files be expanded before using? How?

The MicroDEM setup instructions (page 31) say to click on the "Weapons fan" icon. I do not see this icon on the MICRODEM 7.0 window. Also, at this point, should I be seeing a map?

I am a little confused about the next step.

Uh, yeah. Maybe you would benefit from a visit to the HRD web site at the link
above. It's a control program for Amateur Radios with computer control
capabilities. It's a great program with a lot of functionality. Just check out
the site, really. That should make things clear to you.

Been there, blown up enough diodes to make me want to go back to
relays.  However, that was about 1975, when AMTOR and SITOR were the
next big thing.  High speed reliable RTTY at umm.... 3 characters per
second.
<http://en.wikipedia.org/wiki/SITOR>
At the time, everyone was trying to do SITOR-FEC and ARQ mode using
existing HF radios, including my employer, Intech.  Few of our radios
were really very good at fast TX/RX switching.  The basic spec was
that it had to be less than the flight time from West to East coast.
Speed-o-light is 186,000 miles per second, or 186 miles per
millisecond, or 16msec from coast to coast.  That actual turn-around
spec was something like 35msec as I vaguely recall.  I was thrilled
that the synthesizer PLL would settle down in maybe 25msec, and the
T/R relay in maybe 20msec.  Suffice to say that some major reword was
required to get the timing correct, during which I sacrificed my share
of fried PIN diodes.  Then, we dragged it out for a field test
(parking lot test), and found that the high Q antenna coupler stored
just enough energy to vaporize an ocassional PIN diode.  I got fed up
with expensive Unitrode PIN diodes and substituted cheap 1N4007 power
diodes, which were far more rugged, and lived with the slight increase
in loss.
```

>This isn't a problem with normal split-frequency repeaters, thanks to
>the isolation in the duplexer cans.

True. However, expensive duplexers are a problem with the very narrow TX/RX frequency offset found on 2m, 6m, and 10m repeaters. It's fairly easy on 440 and 1215Mhz repeaters, which have wider offsets.

>Do any of the commercial TDMA systems use the same frequencies for
>base->mobile and mobile->base? My recollection is that TDMA cellphone
>systems operate with split uplink/downlink frequencies.

TDMA is IS-54/136, which is always on split frequencies. There was an HF system in Africa that I worked on in about 1979, that used single slot audio compression, and a single channel. It's idea of time slicing was trivial with a 50% duty cycle, and one cycle every 128 stolen for control. Absolutely nothing was standardized, but was very suitable for use on HF. I suppose it would be easy enough to take one of the HF digital encoders, add a synchronous t/r switch, and you have a workable start. I think this is close, but without full duplex:
<http://www.aorusa.com/others/ard9800.html>

>But "no filtering" comes with its own set of concerns.

Yep. If the repeater is going in any of the buildings where I have equipement, it will need a cavity and ferrite isolator to prevent intermod problems. I know of one building that demands Heliax, no braided coax including LMR-xxx coax, all silver plated connectors, and other draconian anti-intermod measures. Tempest like packaging on all computahs. All I can say is that it works (if you can afford it).

```

For 75 and 80 meters, I use a shunt-fed tower (58 feet high, with a fairly big HF yagi on its top). The home-made tuner, placed at the tower base, has a motorized variable vacuum capacitor in series and a (properly selected) fixed capacitor in parallel. I can so remotely tune the variable capacitor across the 3500 - 3800 kHz range obtaining a perfect match to 50-ohm everywhere in the band. The antenna works fine and I receive good reports.

The only thing which worries me a bit is the very high voltage that develops at the antenna end (about 6,900 Vrms at 3.500 MHz with 2kW applied, growing to about 8,600 Vrms at 3.800 MHz). I am not sure whether such high voltage could be a source of significant losses.

To solve my doubt, I started by precisely measuring the capacitance of the tuner capacitors, and I could then easily calculate the antenna impedance at 3.500 MHz, which resulted to be (18.2 + j 656) ohm.

ABOUT CURRENT
With 2 kW applied, one can easily determine that the RF current flowing through the antenna is about 10.5A, quite higher than the 6.3A figure one would get should the antenna resistance be 50 ohm instead of 18.2 ohm. So, I must expect some more loss in the conductors due to the fairly high current.

ABOUT VOLTAGE
The 10.5 A current flowing through the big 656 ohm antenna reactance causes the antenna RF voltage to get up to 6,900 Vrms at 3.500 MHz. Touching the wire with a (well insulated) screwdriver, you would see a nice Tesla-like arc. I am wondering whether such a high voltage could constitute, by itself, a source of extra loss. Please note that the wire coming down from the tower is connected directly to the vacuum capacitor terminal, with no stand-off insulator. So, I do not see a place where power can get dissipated due to the high RFvoltage, other than perhaps in the humid air (?).

I could probably avoid this situation by changing the tap height on the tower, but I would run the risk of not being any longer able to tune across the whole

3500 - 3800 kHz band adjusting one of the two capacitors, and not both.

Any idea on whether the high RF voltage present on the antenna could cause some significant loss?

Thanks and 73

Tony I0JX

I've never seen that anywhere. Intermod is a math problem. No amount of
silver plating will fix bad coordination.

It could differences in what we call our "building code" (the regulations to be met for new construction, or remodeling). What we use may not meet your local/national code - thus there is no commercial reason to offer them for sale.

Hi Antonio,

Describe the "shunt." (I presume it is a long wire from the tuner,
standing off 10cm or so, up maybe 5 - 10 meters where it attaches to
the tower? Can I also presume that the tower goes to ground at the
base?)

>The antenna works fine and I receive good reports.

And so it would seem this would be the end of the post. But no.....

>The only thing which worries me a bit is the very high voltage that develops at
>the antenna end

End? There are at least two, and perhaps you mean the end of the
shunt at the tuner? If by "end" you mean up at the very top, then
high voltage would be expected (but worry about it would not be
expected).

By this point, there are a lot of gaps in the description (at least
for me).

>(about 6,900 Vrms at 3.500 MHz with 2kW applied, growing to
>about 8,600 Vrms at 3.800 MHz). I am not sure whether such high voltage could be
>a source of significant losses.

You worry about loss, when you receive good reports?

High voltage reveals loss in heat. Corona would be an example, but you don't describe corona. You also don't describe heat.

>To solve my doubt, I started by precisely measuring the capacitance of the tuner capacitors, and I could then easily calculate the antenna impedance at 3.500 MHz, which resulted to be (18.2 + j 656) ohm.

I think you have a sign problem. You are describing a short antenna with inductive reactance (given the height and wavelength, very improbable).

However, this might be the feedpoint impedance at the lower end of the shunt - maybe, maybe not.

>ABOUT CURRENT
>With 2 kW applied, one can easily determine that the RF current flowing through the antenna is about 10.5A, quite higher than the 6.3A figure one would get should the antenna resistance be 50 ohm instead of 18.2 ohm. So, I must expect some more loss in the conductors due to the fairly high current.

Only in the shunt wire. Only if you are using wirewrap wire. Measure the RESISTANCE. Multiply by CURRENT squared. You get WATTs. How many? That is your loss. Now, if you can measure the resistance of your tower, stand very far back because it is about to fall over from being rusted out.

>ABOUT VOLTAGE
>The 10.5 A current flowing through the big 656 ohm antenna reactance causes the antenna RF voltage to get up to 6,900 Vrms at 3.500 MHz. Touching the wire with a (well insulated) screwdriver, you would see a nice Tesla-like arc.

With this statement, it is obvious that you are not touching the screwdriver to the "end" of the antenna (some 15-20 meters above your head).

Current and voltage are not uniformly equal along the length of the antenna. Your beam at the top acting as a top hat might yield some uniformity, but that doesn't come from simple math analysis.

Instead, what you describe is a feedpoint impedance calculation.

>Any idea on whether the high RF voltage present on the antenna could cause some significant loss?

You are working very hard to find a problem that isn't there.

Sounds like you've never had to deal with transmitted intermod.
Consider yourself lucky as getting rid of it is a PITA. Also, not all
intermod comes from mixing in the receiver. TX intermod is real and

preventable. The xmit cavity and ferrite isolator prevent any RF from adjacent antennas from going down the antenna, into the power amp, mixing there with the xmit signal, and having the power amp amplify the intermod.

Google for "intermod suppression panel".
<http://www.google.com/search?hl=en&q=intermod+suppression+panel&um=1&ie=UTF-8&tbm=isch>
<http://www.repeater-builder.com/antenna/ant-sys-index.html>
<http://antennasystems.com/product/sinclair-PC3/PC3113.html>
<http://www.telewave.com/pricelist/impanels.html>
<http://www.sinclairtechnologies.com/catalog/group.aspx?id=32>
<http://birdtechnologies.thomasnet.com/item/components/intermodulation-suppression-panels/81-series?>
<http://www.ferrocom.com/products.htm>
<http://www.taradios.com/IM_Supression_Panels.html>
etc...

Incidentally, my Rotomola UHF MSF-5000 repeater has *THREE* isolators, connected in series, in addition to a band pass cavity filter. Lossy, ugly, but clean.

Next, silver plating is not a magic fix. Getting rid of bright nickel plated cheap connectors *is* a magic fix. I've cleaned up several systems by simply getting rid of cheap connectors and adapters and replacing them with silver plated brass connectors (or just brass as in Heliax connectors).

Google for "Passive Intermod Distortion":
<http://www.amphenolrf.com/simple/PIM%20Paper.pdf>

> Materials: Ferromagnetic materials such as nickel or steel must be eliminated from the current path due to their non-linear characteristics. Brass and copper alloys are generally accepted as linear materials. Tests have shown that nickel plate under gold on the center contact will typically result in a 40 to 50 dB increase in PIM. Stainless Steel in the body will usually give a 10-20 dB increase in PIM.

More:
<https://engineering.purdue.edu/IDEAS/PIM.html> (nice video)
In case you've seen magnets taped to coax connectors, this might explain why.

More on PID.

An intermod study compares transmit freqs as well as input freqs.
Circulators are accepted practice. The intermod study will tell you if
you need more traps, BPF, etc. There is a lot of pseudoscience in
technology (and a comparable amount of "overkill"). By far, the worst

problem I encounter is XM radio on 2.5 gHz and ground radar from airplanes (they like to use tower sites as benchmarks).

I have worked some of the premiere sites (Cedar Hill, Mt. Wilson, South Mountain in Phoenix, Mt. Harvard, Senior Road in Houston, the John Hancock building, the router room at Channel 4, etc.) and I have never seen a blanket ban on LMR because it leaks.

All it takes is ONE user who believes himself to be above
any technical standards in his quest to maximize profit.

These are the same clowns that strip a site of any and all
hardware that isn't nailed down or currently connected to
something.

Or throw together a "repeater" out of junk bought at the
swap meet and nailed to a piece of plywood.

It's not leakage. The problem is the plated steel wire used over the foil wrap on the shield. The steel is non-linear and subject to PIM (Passive Intermod) problems. The aluminum foil to steel junction can easily become a diode if the mylar coating is penetrated. I've seen it with LMR-400 on a lab test similar to the YouTube video that you apparently didn't watch. The problem was bad enough that Times had to conjure a special mutation of LMR-400 with low PIM:
<http://timesmicrowave.com/products/lmr/downloads/126-129.pdf>
I think (not sure) that the only difference is that the braid over the foil is now aluminum.

The initial reaction of most techs is that the PIM is sufficiently low level that it would not have an effect on receiver performance. Wrong. In cell sites, where squeezing every dBm of sensitivity out of the receiver is necessary to deal with perpetually marginal cell phone handset signals, that install cryogenically cooled front ends and tower mounted preamps to do this, can definitely see the effect. Look at a cell site install and try to find anything other than Heliax.

"SITE MANAGEMENT EQUIPMENT INSTALLATION RULES" (sample)
<http://www.repeater-builder.com/antenna/site-stuff/radiositerules.html>

> "C. All cabling from the building to tower including on the tower to the antenna, shall consist of a minimum of 1/4 inch jacketed corrugated copper "Heliax" type cable. Semi-rigid "LMR-400", "LMR-600", etc. cable and non-rigid cable, such as RG8, RG, 213, RG-214, RG8X, etc. will NOT be used as transmission cable exiting the building."

In most cases, this has been extended to include internal coax cabling that carry transmit RF.

Yep. However, sometime they actually have a clue. One of my friends recently orchestrated a site cleanup and purge, emphasizing coax cables and isolators. After the complaining, yelling, and screaming stopped, so did the intermod. On the other foot, the county decided to do the same things on a crowded tower that we were sharing. All the LRM-400 came down, and was replaced by Heliax. Much of the intermod went away, but the mixes generated in the receiver front ends remained.

>These are the same clowns that strip a site of any and all
>hardware that isn't nailed down or currently connected to
>something.

They're probably the same clowns that steal my scope probes that I leave plugged into the scopes at various sites.

I had a weird problem related to unused equipment. There was an unused "smog alert" receiver at one site, connected to an external ground plane antenna half way up the tower. It was turned off as the system was obsolete. Someone noticed that if they unplugged the antenna connector, some of the intermod would magically disappear. The outside antenna was picking up RF from the tower, delivering into the building, and the badly shielded receiver front end was re-radiating it all over the rack. The building manager immediately instituted a reign of terror, demanding that all unused equipment and antennas be removed, resulting in most of the junk exiting the building and tower. There was a slight but noticeable decrease in intermod. Oh well.

>Or throw together a "repeater" out of junk bought at the
>swap meet and nailed to a piece of plywood.

Ahem... You must have been looking at my photos. Please don't do that. Here's our unfinished plywood APRS weather station, built on a plywood (with ash veneer) bookshelf:
<http://802.11junk.com/jeffl/WR6AOK-WX-Station/>
The 2m bottle is not in the picture. I use screws, not nails. There was a good (political) reason to use plywood. Also, the rack in my living room has plywood shelves, as are the radios in my Subaru.

I did not describe the RF ground because I consider it not relevant to my question.

Anyway, the ground system is formed by 64 quarter-wave radials.

Cell sites are a different animal . We were talking about 2-way,
point-to-point, VHF/UHF broadcast type sites. YouTube is pretty intense.

That same diode-like effect also seems to be capable of causing the cable to generate a nontrivial amount of broadband noise, when energized by a sufficiently strong transmitter signal. In simplex applications this seems not to matter, but in repeater applications it tends to cause enough of an increase in the noise floor at the receiver to appreciably de-sensitize the receiver.

The system I work on, was originally build with LMR-type feedlines within the cabinet, and didn't "hear" particularly well. When the chief hardware guru threw out all of those (well-constructed) pigtails, and replaced them with 1/4" heliax... the problem went away and has not returned.

Heliax is good. Double-braid shielded cable (with silver-plated copper braid, not aluminum) seems to be almost as good.

Such is the case on USN ships of my acquaintance. If the ship buys a commercial transceiver and throws the antenna any old place, the front end becomes a mixer. There's a reason why (most) military gear is pricey. It's been engineered not to do that.

Aside:
It's not always an active device that causes problems. I had one ship that was getting massive interference on UHF comm circuits between about 325 MHz to 399 MHz. from a radar operating around 430 MHz. Normally not a problem. The cause was a tangled hunk of wire I found in the field of the radar. It had been used to secure scaffolding during the ship's previous inport period.

Every time the radar lit up that bailing wire, the resulting arcing and sparkling generated broadband RF pulses at the radar's rep rate.

I was climbing around on the mast, looking for just something of the sort. When I saw that wire, I actually spoke out loud to it.

I said, "Well, hello there!" True story.

It's one of several reasons we preached "Topside Housekeeping" to our Sailors during ship visits. Leave nothing on the mast that doesn't have to be there.

Interesting. I always hear people bragging about LMR. Are we using the

term "Heliax" generically? Is semi-flex no good too, (It's all aluminum
and brass metallically isn't it?)

Did your guru make a profit on the replacement cables? How do you know a
$15 can of Cramolin wouldn't have helped just as much?

Tinned copper braid is OK, no?

Yeah, I've seen some of that.  I spent several days finding the
culprit on a UHF repeater where the over the air rx sensitivity varied
```

substantially and erratically. Watching the IF noise level, showed it going up and down with the sensitivity changes. In frustration, I grabbed a broomstick and beat on the accessible coax cables. I eventually found a length of 9913 coax that was apparently involved. I replaced it, and the noise problem disappeared. Inspecting the coax carefully, the outer jacket was slightly corroded and white dust was visible.

>> In simplex
>> applications this seems not to matter, but in repeater applications it

Yep, but the mechanism isn't obvious. All transmitters belch some level of synthesizer or oscillator noise. The notch type duplexer does a great job of getting rid of the noise in the receiver bandpass produced by the transmitter. However, when there's a diode present, the very low level tx synthesizer spurs, or other signals picked up at the antenna, mix with the tx synthesizer noise, and land on the receiver frequency. It's intermod, but instead of dealing with a collection of individual frequencies, it deals with broadband noise. The same mechanism is a problem in broadband mux, broadcast, and cellular systems.

>> The system I work on, was originally build with LMR-type feedlines

Requiring Heliax is a good but expensive solution. Requiring Heliax on initial installation makes is somewhat less expensive.

>> Heliax is good. Double-braid shielded cable (with silver-plated
>> copper braid, not aluminum) seems to be almost as good.

Sorta. I have problems securely attaching connectors to RG-213/u. Unlike the rigid and semi-rigid cables, crimp type connectors are problematic. In addition, much of the RG-213/u floating around is NOT silver plated, but bare copper. That will corrode, and form diodes.

I also don't like the attenuation of RG-213/u. 5.1dB/100ft at 450MHz, while LMR-400 is 2.7dB/100ft at 450MHz.

On 11 Sep 2011 13:32:15 GMT, dave <dave@dave.dave> wrote:

A picture is worth 1000 words:
Heliax:
<http://www.google.com/search?tbm=isch&q=heliax>
LMR type coax:

<http://www.google.com/search?tbm=isch&q=LMR+coax>

I've never heard of semi-flex. Perhaps you mean semi-rigid coax,
which includes aluminum outer jacket coax as used in the CATV
industry? The coax is fine, but where it transitions to a brass or
silver plated connector, there's a problem. In general, it's a bad
idea for reducing PIM (although I use CATV coax because I'm cheap).

>Did your guru make a profit on the replacement cables?

Guru's do not stay in business very long unless they're profitable.
Even the glorified poverty style of guru has to eat.

>How do you know a
>$15 can of Cramolin wouldn't have helped just as much?

Cramolin is now DeOxit and has been reformulated.
<http://store.caig.com/s.nl/sc.2/.f>
It's a total disaster on RF connectors because it contains oleic acid,
which is great for removing oxides from electrical contacts, but
equally good at rotting off the plating from connectors over long time
periods. The reformulated DeOxit allegedly contains a different
anti-oxidant, which allegedly has the same effect.

>Tinned copper braid is OK, no?

Dunno. I never use tinned braid except for some semi-rigid microwave
coax, which is quite stiff. Most often I see tin plated braid. Since
tin is not magnetic, there's no PIM problem.

To run HRD. I'm already aware of it. People who refer to their computers as if they were automobiles use it. I am running my ham radio station on Puppy Linux and fldigi for control and soundcard modes. My computer is an "Everex 2500", which is a little tiny low powered VIA C7D-based system that WalMart tried selling back in 2008 or so. I bought one. Microsoft wants $150 for an OS on a $150 computer. Screw that.

Did I mention that this computer idles at around 25 Watts? Less than
most notebooks?

Cramolin is still alive and well. It was and still is made in Germany,
```

DeOxit is made in the US, Caig used to be the US distributor of Cramolin
products, but went their own way, with a different formula.

I'm not sure which one is the one that you call "a total disaster", but
AFIK neither is to be used for anything except cleaning. Caig sells
solutions (pardon the pun) for use on connectors.

I have them because I can only buy DeOxit in small tubes off of eBay and
still get it shipped here, and that was the only way I could get fader lube,
but I have never used them.

Don't go looking it up and show me auctions of just fader lube, after I
ordered the sets, which did not show I up, I commented to the vendor
that I wanted just the fader lube and now they list it.
They also replaced the missing packages.

Geoff.

Yes... I meant "cable with a solid or near-solid outer conductor".

> Is semi-flex no good too, (It's all aluminum and brass metallically isn't it?)

I think that the key is avoidance of (1) contact of dissimilar metals and (2) ferromagnetic materials. And, you want a cable where you can get a really good electrical contact between the outer braid, and the connector shell. I believe that solder beats crimp in this application, since you end up with a connection which will reliably remain gas-tight and won't oxidize. A good semi-flex would probably be fine, I'd guess.

LMR-400 seems to be dodgy (for repeater use) over several of these issues.

I do like it for simplex applications.

>Did your guru make a profit on the replacement cables? How do you know a $15 can of Cramolin wouldn't have helped just as much?

Nope... he's one of the volunteers in the repeater group. He donates his time, we use donated materials (e.g. the heliax cable, ex-cell-site) when possible, and any supplies the repeater needs are bought from independent commercial suppliers (e.g. the connectors, in this case). He was annoyed at having to go to the trouble of replacing the existing pigtails, but *very* pleased at the result... it turned the system from a "basket of snakes" into one in which the three repeaters in the cabinet can all operate simultaneously and independently without any cross-band interference that we can detect in any way.

We're also sharing the hospital-roof site with at least one cellphone system, one pager transmitter (for several years - gone now), and several public-safety LMR repeaters... and so doing things carefully is quite important!

Both sets of cables (the original LMR and the replacement hardline) had high-quality commercial-grade connectors... no cheap nickel-plated imports. Hence, I do think it's accurate to ascribe the difference in performance to the cable itself.

Cramolin is nice stuff for dealing with connector-to-connector contact issues, but it doesn't do a thing for problems internal to the cable.

Yeah, you have to make sure you're getting the "good stuff", with silver-plated copper braid... and then (I think) solder, rather than crimp.

See http://www.isoconnector.com/cableassemblies.html - "semi-rigid" and "semi-flex" are different constructions.

>Cramolin is now DeOxit and has been reformulated.

Well, sorta and sorta not. Cramolin is still made by the original (German) manufacturer, but isn't easily acquired in the U.S. DeOxIt is made by Caig, who used to import Cramolin but are now making a similar product themselves.

>It's a total disaster on RF connectors because it contains oleic acid,

My recollection is that the instructions which came with Cramolin said that you should clean the remains of the "red" Cramolin (the oxide remover) off of the contacts after de-oxidizing.

They made another "blue" product which was intended to provide some residual anti-re-tarnishing protection... I think it was based on palm oil.

When I use Cramolin (I still have a bit of the concentrate) or DeOxIt on contacts, I follow it with a final cleaning using isopropyl or denatured alcohol (or acetone if I'm feeling really thorough), to remove the remains of the anti-oxidant.

>Cramolin is still alive and well. It was and still is made in Germany, DeOxit is made in the US, Caig used to be the US distributor of Cramolin products, but went their own way, with a different formula.

Got it. All I can find it DeOxit in California.
More detail:
<http://siber-sonic.com/electronics/caig.html>

>I'm not sure which one is the one that you call "a total disaster", but AFIK neither is to be used for anything except cleaning. Caig sells solutions (pardon the pun) for use on connectors.

Different stuff. Most of it is just grease to keep the connectors from oxidizing. The total disaster was what I found on a tower where someone had used Cramolin to clean an assortment of 7/16 DIN and N connectors. The 7/16 DIN connectors were stainless. They turned black and had a rough pitted surface. The N-connectors were silver on brass. The silver was intact, but would flake off in small pieces, exposing the underlying brass, which rapidly turned dark green. Everything had to be replaced. I don't recall how long it took to get to this point but I think it was at least 2-3 years.

If you Google for corrosion characteristics of oleic acid, you'll find that it attacks steels, but is compatible with copper. Not true. Pure oleic is compatible, but add some water and the stuff becomes corrosive.

Oleic acid is a major component (70%?) of peanut oil. You could probably use peanut oil mixed with some organic solvent in place of Cramolin. (No, I haven't tried it).

>I have them because I can only buy DeOxit in small tubes off of eBay and still get it shipped here, and that was the only way I could get fader lube, but I have never used them.
>
>Don't go looking it up and show me auctions of just fader lube, after I ordered the sets, which did not show I up, I commented to the vendor that I wanted just the fader lube and now they list it.
>They also replaced the missing packages.

I mix many of my own chemicals. Most of the tuner lube type stuff is fairly simple. Organic solvent, ionic solvent (water soluble), oxide remover, and some oil:

I believe on of the reasons that Caig stopped carrying it was that it is
too corrosive to put on an airplane and they wanted something UPS/FEDEX
would carry.

Ok, good thing I only use it to clean contacts and that's a drop on the end
of a q-tip or toothpick.

For me those days have passed. Between space limitations, lack of working
area, inability to order those chemicals, etc, I'm going to have to make
do with little tubes sent airmail. Luckily I don't need much and have
all I need for a long time. :-)

Geoff.

Duh...  They carry peanut oil, which is 75% oleic acid, but won't
carry Cramolin, which is 5% oleic acid.  I just checked the 49 CFR
list at:
<http://www.ups.com/content/us/en/resources/ship/hazardous/download/chemical.html>
and Oleic acid isn't listed.  The MSDS sheet shows slightly flamable,
but otherwise safe.  My guess(tm) is the business relationship fell
apart and that the UPS/Fedex story isn't true.

Isn't there any concern for plastic deterioration from the acetone? When I read what you wrote, I cringed, having seen acetone's effect on (some) plastics. Keeping a few four-leaf clovers on the bench?

Yup. My work on USN ships showed me some of that. Within a few feet of any
HF transmit antennas, what they call "standing rigging," things that are
mounted or attached topside, can be energized with hundreds of volts. The
Navy imposes RF RADHAZ and RF BURN zones in selcted topside areas. They're
always marked and sometimes cordoned off with physical barriers.

Didn't Art Bell, W6OBB, former host of Coast to Coast AM, report 300 volts
on his loop antenna?  Even with low current, a kiss from that voltage will
make you fall out of love.

Thanks. I've been calling both types semi-rigid, which is wrong.

No clue on the oil, but my guess would be cheaper mineral oil and some solvent to wash off any residue from Cramolin red. I've never used (or seen) Cramolin Blue.

I use 409 cleaner, which has a pH of about 11, or ammonia window cleaner, both of which should neutralize the acid. Acetone will make a mess of anything plastic and really is overkill. For open frame relays, I sometime use electroless silver to replate the contacts. I also have a diy silver brush plating kit, which I use large contacts.

I represent the not-thinking group. I'm 68 and have been doing electronics seriously since I joined the Navy at 18. OK?

In the mid-1990's, I managed to grab a cable I thought went to an antenna. I connected it to my H-T and made a call. Well, that cable wasn't to an antenna. It went to the input of my TM-221A. ($85.00, if you're curious)

If "Being Careless" were a franchise, I'd owe the fee every year. *sigh*

Perhaps you didn't notice but several of the examples of PIM and rotten coax induced intermod were for non-cellular systems. The problems are much the same with any service type. If you have moderate TX power, magnetic materials in the connectors, and sensitive receivers, PIM might be a concern.

Also, it may not be obvious unless you've worked on a cell site, but the state-o-de-art in radio is currently defined by cellular. The current generation of cellular radios, pre-distorting power amps, tower mounted amps, cryogenic front ends, steerable antennas, channel loading, codecs, and environmental protections, are far superior to what I've seen in commercial radio, and light years ahead of the 3rd hand garbage commonly found in ham repeaters. Yes, cellular is different, but it's also quite superior. If the cellular people think they have a PIM problem, it's probably quite real.

Unfortunately, cellular can't always get everything right:

No chair... standing room only.  It's part of a furniture dolly that I
use to move the two MSF5000 repeaters around the shop.
<http://www.harborfreight.com/1000-lb-capacity-movers-dolly-38970.html>
<http://802.11junk.com/jeffl/K6BJ-MSF5000/backup-repeater.jpg>
It's leaning against one side of the backup repeater.  The shop also
is used for small engine repair, chemistry experiments, general
fabrication, bicycle repair, and radio repair.  Bench work came to a
standstill for 2 weeks while I was waiting for chain saw parts.

It depends on what sort of thing I'm cleaning. You're correct... I
don't use acetone on anything plastic.

Depending on the plastic, either an alcohol, or a light petroleum
solvent (Stoddard solvent, naptha, etc.) is a safer "wash".

True - it's for metals-only applications.

>                                               For open frame

Is that Cool-Amp (powder), or some form of liquid electroless silver?

I've made up (and use) a homebrew substitute for Cool-Amp - silver
chloride and salt, finely ground, and then rubbed in firmly.  Makes a
nice, solderable surface for DIY PC boards.

<http://www.cool-amp.com/cool_amp.html>
That's silver chloride and calcium carbonate powder.  $25/oz.  Ouch.
I've used Cool-Amp immersion plating (it's not really electroless). It
works well for PCB and contact plating.  You might find this of
interest:
<http://yarchive.net/electr/pc_board_silver_plating.html>

What I have is:
<http://www.transene.com/ag.html>
I think (not sure) it's a silver nitrate, ammonia, sodium hydroxide,
and who knows what else mix.  One catch is that it has to be applied
warm, which is somewhat of a challenge.  I'm sure easier to use stuff
exists, but I didn't pay much for the 1 oz bottle which seems to be
lasting forever.  When I run out in about 10 years, I'll look at
alternatives.

More:
<http://www.finishing.com/faqs/silverathome.shtml>

Nice, but don't use salt.  Use calcium carbonate instead.  Salt
(sodium chloride) might precipitate the silver out at silver chloride.

Until the RF Ground is described, You can't make any definitive
decisions, about any kind of Marconi Antenna, no matter how it is feed.
This is common problem with many, less than educated, Hams, that try and
design Antennas Systems for HF. Most of the Losses in these designs are
in the RF Ground System, and not in the Radiators. Just Say'en....
YMMV...

I am not interested in knowing the overall losses and making decisions on my antenna . I am just interested to know whether someone has experience on the effect of very high voltage on the antenna terminal. And for that very purpose the ground system is not relevant.

No useful answer received so far.

The problem of this newsgroup is that people not knowing how to answer a specific question, reply to other questions, just to write something.

Not so much full duplex, but single frequency half duplex, with
negligible time delay (implying <100ms frame time) between Rx and Tx.

Sure.. 802.11 is half duplex on a single channel, for instance.

Lots and lots of radars have fast and reliable T/R switching at pretty
much any frequency you care to name from DC to light.

TDMA cellphone uses split bands probably because it was on top of
existing AMPS systems. There is also a frequency allocation issue (e.g.
no need for new licensing). Having separate forward and reverse bands
also helps with frequency reuse and near-far issues.   I hardly think
that hams are going to carpet the country with repeaters to the extent
that cell sites do.

You don't need that big a guard time if you keep track of how far you
are from the repeater and adjust your timing appropriately (that's what
a lot of systems do, and it's what was used for coarse position finding
in the phase 1 E-911 systems). That was an ordeal in 1980s to
implement, but today, it's in the piece of cake area, at least from an
implementation complexity and hardware standpoint. There is probably off
the shelf IP for it, too.

Keeping the BW down

Yes, but on the other hand, standard cellphones use 8kbps and while the quality isn't great, it's good enough. Of course, that gets us into that whole "any decent codec is tied up with licensing problems" rat's nest.

The beauty of usenet is it allows all sorts of characters to post. Typically, in response a simple question it turns into some insane "How esoteric and complicated can I make this?" contest.

So, with that thought in mind....

You have a rotor, you have two wires between your radio shack and the rotor.

Since everyone seems to think that broadband over power lines is such a "Good thing(tm)" here's a solution to your problem.

Use your two wire feeder to supply a fixed AC voltage to run the controllers and the rotator.

Feed a digital control signal up the power line to tell the rotor which way to turn.

Feed a digital signal back down the power line with the telemetry to feed a display of which way the rotor is pointing.

Obviously since you have a bi-direction data stream on the power line to the rotor, you can get as complicated as you want with the amount of extraneous details. Such as slow start, brake clutch on and off.

In fact, since you're already in the roof, add a weather station outside and feed that data back down too. ;-)

I like that wristwatch concept. But the quoted passage gave me another idea. If the stalled rotor current is appreciably higher than the operating current, then that's his end-of-travel indicator, right there. I can check it myself and the OP will also need to.

That's a pretty good assessment. I'm even willing to put up with it for the price.

The way I figure, if I have a professional business that I need to buy equipment, I'm going to buy top notch equipment that I can depreciate as part of the business.

In my personal life, I have a bit tighter of a budget. So I'm willing to tighten screws and do the final QC on the stuff. I'm going to open the case and have a look around anyhow.

Guys, guys, when I wrote asking what I thought were a couple of simple questions just to clarify some points, I never thought it would end up creating such a stir. Don't get me wrong, I am enjoying all the technical back and forth communication, it's a whole lot more than I could have imagined.

I just wanted to pop in to say thanks to everyone while the thread is still active. It's turning out to be quite educational, I really appreciate it. Now, I am off to try to catch up with the latest replies.

73, Renee

You're building a CW radar, basically.

That's how near field ranges work, too.

>You're building a CW radar, basically.
>That's how near field ranges work, too.

Yep. Also known as a proximity detector and possibly a really bad interferometer. I can see cars driving by, people moving around in the house, trees swaying in the wind, and the opening and closing of doors and windows. These are all easy to identify on the sweep because they all move around. Only the major dip in the VSWR curve, near resonance, remains fairly stable.

Back to MFJ bashing...   On my desk is yet another MFJ-259B for repair, probably with the two blown shottky diodes that I previously mentioned. One of the local hams heard me talking about the problem over the local repeater, and decided that maybe I could fix it for him. Usually, they wait until the week before Field Day for such repairs but he's installing a tower next week and wants it fixed yesterday. Sigh.

Have you discussed this with Martin Jue? I think it's rude to bad-mouth a fellow ham behind his back. I don't see how the diodes are a problem, if you follow directions. If you live somewhere dusty or snowy and dry enough to make static, use a gamma match or an UnUn or some other means to keep your antenna at DC ground. I have been using germanium diodes for 50 years and can't remember frying one in a small signal RF application. What does Martin say about bleeder resistors?

I have a 4" pigtail around the ground lug and a male banana plug on the end that lives in the middle of the SO-239, unless I am making measurements. I use the banana plug as a shorting stick to neutralize any residual capacitive charge in the device/coaxial cable under test. Center conductor to cable ground. If I am especially concerned I'll groung the 259B to my extensive safety ground system. When dealing with little diodes you always want to make sure none of the sparks go through them. Ground, ground and ground.

>Have you discussed this with Martin Jue?

No. I don't own an MFJ-259B. This is my 3rd(?) repair for what appears to be exactly the same problem. I don't see how calling MFJ will prove anything as they are apparently aware of the ESD problem. See quotes from manual below.

I also reverse engineered the MFJ-1800 antenna, and also decided that it has a problem. I have not called MFJ on these issues. Too busy and too lazy.

>I think it's rude to bad-mouth
>a fellow ham behind his back.

Would you prefer I keep it secret and not tell fellow hams how to fix it and why I think they blow up? I believe that I clearly labelled my guesswork as conjecture and not fact. If hams were only allowed to discuss things that are absolutely certain, the airwaves would be silent.

>I don't see how the diodes are a problem,
>if you follow directions.

The units that are failing are not mine. I have no control over how they are used.

As I vaguely recall, one failed while connected to some HF wire antenna, the 2nd failed while plugging in a variety of calibrated loads on the bench, and the most recent failed while attached to a mobile HF antenna. It was difficult to determine the exact cause of each failure because the unit did not just die, but instead started producing insane readings. In all cases, the user thought something was wrong with the antenna or loads, not the MJF-259B.

>If you live somewhere dusty or snowy and dry
>enough to make static, use a gamma match or an UnUn or some other means
>to keep your antenna at DC ground.

Attach a high impedance voltmeter to a wire antenna blowing in the wind and note the DC voltage produced. In my area, the humidity rarely goes below about 30%, so static build up should not be a problem when attached to an antenna. Currently, the humidity is 80-90% (morning fog), but when we get the hot dry winds from the desert, the humidity will drop sufficiently low to cause problems for a few daze.

What I believe is killing the diodes is not RF. It's the user building up a static charge on plastic seat covers, synthetic clothes, plastic carpet, etc, and discharging it into the antenna connector when plugging in the antenna connector. Incidentally, one of my customers with chronic equipment failures was traced to a negative ion generator, which produced impressive high voltages on nearby object.

>I have been using germanium diodes
>for 50 years and can't remember frying one in a small signal RF
>application.

How many of these germanium diodes were directly connected to the antenna connector?

Apparently you missed my previous rant on the topic. See the schematic extract of the RF section at:
<http://802.11junk.com/jeffl/crud/MFJ-259B-RF-section.jpg>
Notice the directly connected diodes. The diodes in question are

Avago HSMS-2820 zero bias shottky diodes.
<http://www.avagotech.com/docs/AV02-1320EN>
15V Max PIV is rather low. It won't take much voltage at the antenna go exceed 15V. The two 47K resitors going to 0.01uf bypass caps make an effective ground to any fast risetime voltage spike at the antenna. An important clue is that BOTH D3 and D4 appear to be blown each time, which implies an external failure, not a component failure.

>What does Martin say about bleeder resistors?

I don't know. I haven't discussed this or any of my allegations with him or MFJ support.

>I have a 4" pigtail around the ground lug and a male banana plug on the

>them. Ground, ground and ground.

Yep. That's a good way to provide some protection. However, there's no protection while you're juggling connectors when you run the risk of a static discharge to the center of the coax connector.

I don't recall reading such a procedure in the user manual. However, there are plenty of warning:
<http://www.mfjenterprises.com/pdffiles/MFJ-259B.pdf>
In section 4.1:
   WARNING: NEVER APPLY EXTERNAL VOLTAGES OR RF SIGNALS TO THE
   ANTENNA CONNECTOR.
and in 5.1:
   WARNING: NEVER APPLY RF OR ANY OTHER EXTERNAL VOLTAGES TO THE
   ANTENNA PORT OF THIS UNIT. THIS UNIT USES ZERO BIAS DETECTOR
   DIODES THAT ARE EASILY DAMAGED BY EXTERNAL VOLTAGES OVER A
   FEW VOLTS.
and in 5.2:
   WARNING: NEVER APPLY EXTERNAL VOLTAGES OR RF SIGNALS TO THE
   ANTENNA CONNECTOR. PROTECT THIS PORT FROM ESD.

Clear enough. It would appear that MFJ is fully away of the fragile nature of the input circuitry.

Hmmm.... The problem might be the SO-239 connector. When you plug something into that connector, it connects the center pin first, and then the ground. If it were replaced by an N connector, the ground would make contact before the center pink, thus offering some added protection. I'll see if the connector can be replaced.

<http://www.w8ji.com/mfj-259b_calibration.htm>

> Most Likely Failures
>
> Other than manufacturing errors, the detector diodes clearly stand out as the most common problem. They are the most easily damaged devices in the analyzer. If you have a sudden problem, it is most likely a defective detector diode. Diode damage almost always comes from accidentally applying voltage on the antenna port.
>
> Why are the diodes so sensitive? In order for the detectors to be accurate within a fraction of a percent (one bit), detector diodes must have very low capacitance and a very low threshold voltage. This means the diodes, through necessity, must be low-power zero-bias Schottky microwave detector diodes. The same characteristics that make them accurate and linear cause the diodes to be especially sensitive to damage from small voltage spikes. ALWAYS discharge large antennas before connecting them to the analyzer! Never apply external voltages greater than 3 volts to the antenna port!

and

> Because the detector is broadband and because it is dc coupled to the antenna, any external voltage across the input port causes measurement errors. It is the accumulated voltage of multiple sources that is most important, not the strength of any individual signal. Because of that, large antennas should be tested at times when propagated signals in the range of the antenna's response are at minimum strength.

W8JI designed the MFJ-259b.

Hi Jeff,

I'm sure you are perfectly aware of the single point of failure in
that generality.

Few Caps exhibit 0.01uF (when so marked) to transients (where it is
presumed they will exhibit 1/2*pi*f*c reactance to the risetime).

When we (silverbacks) got into this game, (the preferable) mica caps
were available, snipped out of the nearest sacrificial TV or radio.
Trying to read those several styles of color coding was the biggest
hurdle, but I had plenty in my junk-box.

Ceramic is ubiquitous, now, and far from choice in these matters,
unless you do deep research (maybe).

You got any favorites that respond to this?

I am? Ummm... well, I guess so.

>Few Caps exhibit 0.01uF (when so marked) to transients (where it is
>presumed they will exhibit 1/2*pi*f*c reactance to the risetime).

True. They all have some internal resistance to overcome. However, that's negligible resistance when compared to that of a static blast. Static electricity has lots of potential (volts), but is only able to deliver small amounts of current. That's why we don't get electrocutes by the potential (voltage) difference between our head and our feet. Dividing the large voltage, by the tiny current, results in a fairly substantial source resistance. I'm too lazy to look it some real numbers, but I'm sure it's in mega ohms. The 47K resistance, and whatever ESR the 0.01uF contributes, has little effect on the energy delivered to the shottky diode.

Incidentally, if the source resistance of the static blast was much less, then the diode would not simply be fried. It would probably explode.

>When we (silverbacks) got into this game, (the preferable) mica caps

Dumpster diving in Henry Radio's trash can in West Smog Angeles was one of my favorite after skool exercises. Salvaging old TV chassis and dead tubes were the grand prizes. Silver mica caps came a close second.

>Ceramic is ubiquitous, now, and far from choice in these matters,

>unless you do deep research (maybe).

Ceramic is cheap. I was a big fan of porcelain caps from AVX in big power amps. If you wanna handle current, there's nothing better. Silver mica would get hot, ceramic would explode, and everything else was either too big or too expensive.

Incidentally, I don't think they make 0.01uF silver mica caps. The biggest I played with were in antenna tuners at 4700pF (or should I say uuF for nostalgia purposes).

>You got any favorites that respond to this?

I don't understand the question. Favorite what?

It goes beyond that. Extrapolating from power applications hides the defects of ceramic.

At HF/VHF and above, successful applications comes from throwing uF solutions at pF problems. Ceramic's performance reveals inductive reactance above 1-10 MHz. ESR also exhibits the same turn-around in the same frequency range. Ceramic temperature coefficient is (Y5V) goes into the toilet in weather that most of the south and eastern seaboard has seen this summer. XR7 voltage coefficient causes capacity to plummet at the voltages you offer for static. Over time, ceramics lose capacity for simply having been in service for a while.

Aside from that, they work fine.

> I was a big fan of porcelain caps from AVX in big
>power amps. If you wanna handle current, there's nothing better.

However, those ceramics are 1,000 times (min.) larger than what you have recommended. They serve an entirely different agenda.

AVX discusses these issues in much the same terms (for those larger caps too) at:
http://www.avx.com/docs/techinfo/mlc-tant.pdf

>Incidentally, I don't think they make 0.01uF silver mica caps. The
>biggest I played with were in antenna tuners at 4700pF

Where there is every chance that one silver mica head-to-head with the ceramic actually exhibit better performance (protecting the diodes). Perhaps with the scarcity of silver mica, however, 10uF ceramics would make do (it is not like any precision is demanded to force a selection of 0.01uF which is boilerplate recommendation from the 50s).

I learned to ground everything working on transmitters the size of houses. The B+ is bled and grounded when you open the door, but you still ground anything metal before you touch it. It translated nicely to CMOS procedures on the bench. I am a grounding fool because I know any conductor can store a charge lethal to solid state and that any friction produces a charge. (I humidify, too!)

Such an extreme RF environment is not necessary to blow up the diodes.
```

None of the 3ea MFJ-259B boxes that I replaced required a transmitter the size of a house to blow up. Much as the protective procedures that you are recommending are genuinely useful, the instrument first has to protect itself.

Assuming they were all fried by ESD, I tried to conjur a method that would protect the existing design. As simple bleeder resistor to ground will only help under trivial situations. The worst case senario, of holding the instrument in one hand, and plugging in a PL259 that is connected to an ungrounded antenna with a large static charge, is all too common. Changing to an type-N connector will help because the grounded shield is connected first, instead of the center conductor, as in the SO-239.

Back to back diodes might work if the RF levels are low enough. The non-linearity of the diodes will cause measurement accuracy problems and rectify any off frequency RF going into antenna connector.

I'm tempted to try 1:1 RF broadband transformers which should work over octave frequency ranges. Better yet, a tuned 1:1 RF xformer, to improve the front end selectivity so that it can be used in an RF polluted environment[1]. That would work, but will also be very clumsy and expensive.

I know of several devices where failure is sufficiently common, that spare parts are included with the instrument, and the components are in easily accessible sockets. While not a great solution, it does make some sense.

Other than attaching a grounded anchor chain to the MFJ-259b, spraying holy water around the area to increase humidity, or carrying various anti-static protection devices, do you have any suggestions as to how the instrument could better protect itself from ESD?

[1] Attaching a wattmeter to the typical VHF antenna on a mountain top that is colocated with FM/TV xmitters will show a watt or three of RF. The front end of the MFJ-259b is not going to like that.

That's not a problem. In order to get obtain decent bypassing across 5 octaves of bandwidth (2-30MHz), one needs to have multiple capacitor values and types in parallel. The self-resonant characteristics of the capacitors is the limiting factor. At some frequency, every capacitor, and its associated lead inductance, will exhibit an impedance dip commonly known as series resonance. Below this frequency, the capacitor will look ummm... like a capacitor. Above this frequency, it will be more like an inductor.
<http://www.ecircuitcenter.com/Circuits/cmodel1/cmodel1.htm>

None this has anything useful to do with the 0.01uf caps in the
instrument. The diodes are in series with 47K resistors, which are
much larger than any inductive reactance that the 0.1uf bypass
capacitor might present. Since the MFJ-259b only works well up to
maybe a 10:1 VSWR or 5Kohms, the 47K is sufficiently larger than
whatever reactance is presented by the 0.01uf to make the capacitor
characteristics to not be an issue.

While component selection and circuit design are interesting topics,
the current problem is MFJ design quality, MFJ-259b, ESD protection,
and chronic detector diode failures.

Don't know.....

USB is snap, but I cannot for the life of me find the AM, LSB, RTTY,
or CW settings on my browser. As far as that goes, Firefox doesn't
even have an S-Meter!

$40 is sounding like a good deal. (Hope they have a cheaper app for
my Android.)

I just downloaded the free trial zip file and scanned it. It came up clean and had a size about 3 MB. I set up to unzip it and repeat the scan, but the unzipper reported no files to extract. There were no other errors reported, like cannot find file, corrupt file -- simply no files.

Others, please post your results if you try the free trial download-and-unzip process. TKS.

Sal

Argh. I just started working on the analyzer, and found a few errors, all of which are my mistakes.

1. The antenna analyzer that arrived (3 days late) today is not the expected MFJ-259B but an MFJ-269. The difference is that the MFJ-269 goes up to UHF frequencies. The front end is similar, but not identical.

2. The MFJ-269 has a type-N connector, while the MFJ-259 has a UHF SO-239 connector. So much for the idea of substituting a type-N connector.

3. Despite my idea of installing a bleeder resistor on the antenna connector to drain off the static charge, the antenna connector already shows 50 ohms resistance to ground. I missed this path because of the rather difficult to read schematic of the MFJ-259 RF section at:
<http://802.11junk.com/jeffl/crud/MFJ-259B-RF-section.jpg>
The path is from the antenna connector, through R24, L11, and then to ground.

The MFJ-269 schematic is easier to read at:
<http://802.11junk.com/jeffl/crud/MFJ-269-RF-section.jpg>
which goes through R88, L12, and then to ground.

What bugs me is that the diodes are blowing up despite this rather low resistance to ground. Either hams are finding some rather high power ESD sources with which to blow up their analyzers, or some other failure mechanism is involved.

I haven't finished working on the MFJ-269 quite yet. A report and
photos when I'm done.

I've had more than one device damaged while operating around High power equipment, with probable RF in the shack excursions. My MFJ analyzer, an old Sony camera that had it's floppy drive head destroyed, and a couple other things I cannot remember.

I haven't had any problem with the analyzer since installing my dummy load on it.

But that brings up something interesting. You're reading 50 Ohms on the input connector? Isn't that going to make *all* readings somewhere near 1:1?

Simply change the extension to rar instead of zip and it will extract just fine.
This does not instill confidence in this person/company. I only downloaded it to
check for you, and now we have the answer.

Is it possible that 50 Ohms at DC is much higher Z at MF/HF/VHF?

That is an internet radio tuner with fake buttons. $40 is a lot of money
to spend on make-believe. You can buy a real radio for $40 (a nice one
if you shop around).

Sure, salvage some components out of some dead mice or printers and come up with an optical positioning indicator using the salvaged IR emitters and receivers. A simple cardboard disk with slot(s) that will let you know when it is in certain positions. The more you use, the more accurate the positioning. You could make it simple, or more complicated by encoding the signals. You didn't say you couldn't run new wires, just asking if you could send a control signal down one of the wires already there, so I hope this isn't a complete waste.

Yeah, I get it: knowledge base software (shouldn't it be knowledge
baseD software?).

Does it use fact base(d) data, or is it belief mode compatible with
Rick Perry science? The simple entry of his name guarantees 34
Million hits in search engine traffic. I would suspect all of that is
free user generated content and tea party organized.

Thanks, Bob,
```

Funny but unrelated to this file, I downloaded a different .rar a few days ago and discovered it needs an extractor I didn't have. Now I really have to get that rar extractor. Who owns the rar code rights and why do they hate zip??? :-(

That changes things for me. Over and above ham gear, I already have a dozen
or so real radios, a standalone Internet radio (Livio) and I have
I-Heart-Radio (free) on several computers.

I was imagining this download was a client front-end for a bank of SDRs
hooked to servers, a la a multi-user remote base. Guess not.

I've used 7-zip for years and haven't needed any other program to
compress / decompress files. It's free and does a damn good job at
compressing files too.

 Are you using WinRAR? It's pretty much the de facto standard in the binary
groups. As I told the OP, I wouldn't trust any program that archives a file in
RAR and labels it as a zip format. I suspect this program does it to avoid
having to pay license fees to use a what many feel to be a superior archiving
program format. Apparently the archiving program thinks that RAR is better as
well otherwise I think he would stick with using the zip archive code.

If you look at the circuit, there is a DC path from the centre pin, via the 50 ohm resistor that forms part of the measurement bridge, and an RFC to ground. That would look like 50 ohms at DC, but it will not prevent the measurement bridge working in the way you suggest.

But the reality is that people do damage these things... and so the method you suggested earlier is not likely to be sufficient to protect them.

I am careful to avoid connecting an instrument of this type to an antenna system unless I have drained any static charge first, and avoid other transmitters on air nearby.

An easy trap is to connect the analyser or the like to an antenna, then start working on the antenna without considerig the risk of introducing a spike during the work.

Painful, but worth disconnecting immediately after each measurement. Not as painful if BNC connectors are used.(Why did they build those things with SO239... don't answer!)

I think you are correct. I do think that more care needs to be taken
with these devices than with a lot of other electronic items Hams use.
I liken them to RF attenuator blocks. You see a lot of them in company
repair shops, because people are often trying to put too much power
through them.

After getting the new replacement analyzer, and using the dummy load,
and I do the static drain too, plus I keep it away from other people,
it's lasted FB.

I used to have a Sony Mavica MVC-FD73 camera. Nice camera for 640x480 closeups. I gave it as a present to a friend, who bashed in the LCD display. I repaired it, and she bashed it in again. I gave up.

Per one of my previous postings, none of the failures coincided with any high power RF nearby. One was connected to an antenna when it probably failed, but there were no transmitters active. I've tried interrogating the owners and none claim that they did anything potentially destructive. I've been assuming it was ESD, not RF that is killing the diodes, but I'm not sure.

I just tested the diodes. 3 diodes were open, one was ok.

>I haven't had any problem with the analyzer since installing my dummy
>load on it.

Probably a good idea.

>But that brings up something interesting. You're reading 50 Ohms on the
>input connector? Isn't that going to make *all* readings somewhere near 1:1?

Owen answered that question. L12 (100 uH) is in series with the 50 bridge "load" and therefore allows measurements to be made without padding the antenna with an additional 50 ohms.

I threw together a web page on the MFJ-269 repair:
<http://802.11junk.com/jeffl/MFJ-269-repair/>
Hopefully, this will help anyone following my succession of mistakes and screwups. I'm not really done as I want to verify that it's working correctly and hopefully not require recalibration.

Incidentally, no lock washers on any of the screws inside.

That is probably key, don't trust other people... and be pretty wary of one's self!

It is interesting you mention the Other Persons thing... I am in the process of drafting a web article commenting on the advice that is so common these days on online fora, "can you borrow an analyser?..."

This is almost always offered to some newbie who is having trouble "tuning up his antenna".

Most don't understand complex numbers, impedance, transmission lines, etc etc and someone tells them get an analyser and tune for resonance. I can only guess that the advisers are equally lacking in knowledge and experience, but I will concede that the analyser dumbed down to a VSWR meter with self contained RF source than can be tuned outside band limits, can be a pretty handy thing.

But despite the fact that adjusting many, if not most antennas for minimum VSWR is the sensible objective, the resonance brigade chimes in with make X zero looking into some arbitrary length of feed line, a condition which isn't always associated with minimum VSWR and may actually not be achievable. Some newbies have clipped their mobile whip away to make that discovery, but perhaps without understanding that it was a likely outcome from that strategy.

So Mike, it is likely that someone borowing an analyser to fix a problem wont obtain real benefit, but may damage it in the process.

Owen

Don't waste your time. If you download a zip file that is really a rar file,
or some other mislabled monstrosity, it's usually a scam.

Make sure your virus checker is a good one and it is up to date.

Geoff.

Perhaps not intentional Ham transmissions.

Roy often counseled about how his experience included many interfering
commercial sources. And this in a rather remote reach outside
Portland, I believe.

The first step to solving a problem is to blame someone. I prefer not to blame hams.

Actually, I lied. Two of those that I've repaired were attached to antennas. However, the locations are not conducive to having nearby transmitters. One is in the deep dark forest, where the nearest neighbor, much less nearest possible RF source, is about 1/2 mile away. The other lives in a nearby rural area. No forest, but also no nearby transmitters. However, it's possible that the transmitter in question may have been one owned by the hams in question. Keying a nearby HT or mobile might have been the culprit. Dunno.

>Roy often counseled about how his experience included many interfering
>commercial sources. And this in a rather remote reach outside
>Portland, I believe.

Attach a wattmeter to any VHF antenna on a mountain top with FM/TV transmitters, and you'll get a watt or more of RF indicated. Nice way to blow up the instrument.

>"No one ever expects the Spanish Inquisition!"

The Spanish Inquisition had quite a bit of support from those outside the clergy. Much of it was about confiscating the property of alleged heretics. When it grew in size to become a source of regular revenue, it became an institution (much like our war on drugs). It fizzled out when they ran out of victims.

At this point, I don't know what is causing the failures. However, I do know what to do. Add a dummy load and buy some more diodes.

```

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

 radio/personal-intro
 Subject: Guide to the rec.radio Newsgroups
 Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
 Last Posted: 9 Nov 2001 06:18:17 GMT
 Posting-Frequency: 15th of each month

```
One significant omission, requiring immediate updates, for this article      |
is that it does not mention newer amateur radio newsgroups created since     |
it was written, including:                                                    |

 rec.radio.amateur.antenna                                                   |
 rec.radio.amateur.boatanchors                                               |
 rec.radio.amateur.dx                                                        |
 rec.radio.amateur.equipment                                                 |
 rec.radio.amateur.homebrew                                                  |
 rec.radio.amateur.moderated                                                 |
 rec.radio.amateur.space                                                     |
```

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

What about VoIP using 802.11 as the link. These days, that might be
easier than trying to cobble up a 440 remote link.

How fine is fine?

That last time I did that (about 30 years ago), on a commercial system, there was a huge difference in transmit and receive footprint. Some locations could hear but not talk. Others were the other way around. Either way, the customers were not thrilled. We went back to one antenna per radio.

We then repeated the same mistake with a common receive antenna at the very top of the tower, followed by an RF amp, and then an 8 way splitter. Attach 8 receivers and you only need one RX antenna. Unfortunately, the amplifier was too easily overloaded, and the splitter did not provide sufficient isolation to prevent the local oscillator leakage from creating new receiver spurs. I later added cavities and isolators to solve that problem, which increased the cost sufficiently that 8 TX/RX antennas would have been cheaper. (Except for the tower space rental, but we owned the building and towers). Also, with a single RX antenna on 8 radios, it makes a great single point of failure for lightning hits. It was easy to tell if the RF Amp had taken a hit. The office would simultaneously get dozens of irate service outage calls (These were community repeaters with up to 15 customers per repeater). I would never want to be the top antenna on a tower, no matter what the range benefits.

9 repeater in one rack. Notice the lack of duplexers.
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/Santiago-01.html>

Here's the corresponding transmit antenna intermod generator:
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/LoopMtn02.html>
The receive antenna is behind me, on top of another telephone pole.

Yet another great idea was to physically separate the transmitter and receiver buildings on a mountain top. That was Verdugo Pk in the San Fernando Valley. Sorry, no photos handy. This had some real advantages, especially at low band (30-50Mhz). The problem was that with all the transmitters jammed into one building, with little physical isolation among the antennas, there's was considerable intermod caused by the various TX mixes. Since the original justification for this great idea was to solve the intermod problem, this was also loser.

Much as I don't like duplexers, isolators, cavities, lightning arrestors, fat coax, and omni antennas, the combination is the solution that seems to work the best. All the other great ideas are far worse, more expensive, or deficient in some manner.

<http://802.11junk.com/jeffl/pics/Old%20Repeaters/>

Guess what's happening with this antenna problem?
<http://802.11junk.com/jeffl/pics/Old%20Repeaters/slides/LoopMtn03.html>
Incidentally, that's where I was cleaning up the mess and almost picked up what I thought was a piece of black coax. It was a snake.

Good question.  Coverage was entirely satisfactory over the entire island
and several miles up the Overseas Highway.  I never used anything more
exotic than a rubber duck.  However, Key West is small and all the keys are
very flat.

Thanks for the advice and information.

I'm not in the US. 3Mhz split is more than my entire 2m band. :-(

Acutally that's the real purpose of the whole experiement. We are looking
at setting up a system of internet linked remote inputs (and possibly
low power local outputs) using Linux and SVXLINK.

Right now the final destination is an Echolink type node (SVXLINK also
acts as an Echolink server), but one of the things we wanted to experiment
with is an actual repeater.

Thanks,

Geoff.

Jeff Liebermann wrote:

> That last time I did that (about 30 years ago), on a commercial system, there was a huge difference in transmit and receive footprint. Some locations could hear but not talk. Others were the other way around. Either way, the customers were not thrilled. We went back to one antenna per radio.

That's basically our problem. The repeater we want to use was developed with the criterea that if you parked your car, turned on your 25 watt or higher radio with a 5/8 wave whip and was able to "kerchunk" the repeater, the area was "covered". This coverage was mapped out around 1990.

Since then population has expanded, new housing has been built and new hams have become licensed. 2011 critera is in order to be covered, a ham with a watt HT has to be able to be understood.

The main repeater in question is able to reach the sea twoard the north west to the southwest (about 35 miles), but can't even be heard 2-3 KM to the north in spots, and has almost no reception to the southeast.

Our proposed solution is not radio links as they are a expensive, need to be mainainted on site, etc. Internet remote receivers are very cheap, for example, an HT an interface to the computer and an old P4 (needs built in ethernet) makes a useable one and costs a couple of dollars a month in electrcity. Obvously the location has to have decent internet bandwidth with 64k bits per second spare.

Performance can be improved with a better radio and antenna, but in some places, there is only one ham that needs to be "covered".

There may even be real money for real equipment later, but not now.

Geoff.

That's our problem. Jerusalem is high (3,000 feet ASL) and loaded with hills. There are spots in the city where there is no cell phone coverage. The cell phone companies go nuts trying to fill the holes, but there is a lot of NIMBY here.

At first they used (or planned using) an FM link on 23cm, then they
switched to digital voice over 802.11a (6cm), then to 802.11g on 13cm,
and I think they now use a wired internet connection.

If you have two antennas you don't need a duplexer. Just notch the
transmit from the receive antenna.

I think that is what he is asking.  Can he takes his duplexer and use
it as an extra sharp notch filter for his receiver.  One "side" is
already set up for that purpose.  He is asking if the "side"
originally intended for the transmitter can be used to further filter
the receiver.

One wonders why someone isn't pushing for a digital TDMA scheme for amateurs. You could build a very nice full duplex repeater on a single frequency that way. Sure it's totally incompatible with current FM repeaters, but then, D-star isn't totally compatible either. D-star and it's ilk are sort of half measures in that sense.

No filtering, much less intermod issues in multi station at onee site systems... all kinds of good comes of it.

Digital schemes on HF to replace SSB I can see having real trouble (the biggest is the lack of a "party line" capability, the other is the long propagation delay on HF paths), but on VHF and up FM, you already have a "one person talks at a time" by virtue of the standard FM demodulator.

   The coax is RGS-303, 50 ohm coax. PTFE center insulator, FEP jacket.
http://wireandcable.thermaxcdt.com/item/high-performance-coaxial-cabl...
    The coax has 4 toroids slid over it.

Hi Jeff,
I see MFJ now has a Bi-Quad 12dbi antenna.
http://www.mfjenterprises.com/Product.php?productid=MFJ-1804
If I send the the dimensions....
Just kidding!
Thanks for all the work.
Mikek

Oh, they have their problems!

I picked up an MFJ-949E manual HF tuner at a local swap meet . At home, I
opened it to give it the once-over. Good on me. Most of the nuts and bolts
in the RF path were quite loose and none of them were completely tight --

and we're talking about my using a nut driver with three fingertips, not a
lug wrench with two hands.

And I assume you bought it used. I don't remember seeing
MFJ vendors at the swap meet. So.... The hardware was loose.
You don't know for a fact that it came from MFJ that way.

Or, the original purchaser had no idea why it didn't work

when he bought it new and sold it without any comment other
than "New in the box".

I had that happen with an SO-239 connector on the back of an MFJ tuner. One of the pop rivets was loose, possibly from the factory, more likely from being banged around my home.

I drilled out the pop rivets on that connector (the others were all fine) and replaced them with bolts, nuts and lockwashers. It's fine now.

While we are talking about MFJ products, I had a 20 meter CW rig from them that I bought in 1995 stop receiving properly in 2010. I filled out a "support request" on their website and the guy who designed it sent me an email.

Geoff.

A drop of anaerobic threadlocker would be a better solution.  Most
commercially manufactured equipment these days doesn't use lockwashers
for good reason, unless it's a "heritage design" where they're counting
on the thickness of the washer or something like that.

Picking the right chemical is important (wicking vs non-wicking, various
break strengths, various cure times, etc.). Don't use Loctite 241 red on
4-40 hardware you ever want to remove.. it's stronger than the metal..
the green 290 is great stuff for "post assembly" use.

A good number of years ago I bought the MFJ-948 tuner. It was bought new from a large dealer at a hamfest. Same thing. It raddled when I got it home. Atleast one nut if not more was loose in the box. I had to tighten many of the screws/nuts in it before I put it on the air.
I compaired the wattmeter to a Bird and a good dummy load. It was way off. When calibrated on one band, it would be way off on another. Finally calibrated for 20 meters and let it go at whatever on the other bands. All I ineeded for is to watch the reflected power and tune for minimum. I have several other meters to actually check the power if I need to.

The only other MFJ item I have owned was a 1270 Packet unit. First one was bad out of the box, but to their credit, when I called, they shipped me a new one and I got it in about two days. I sent the other one back. The new one worked as I expected it to as long as I had the packet station going.

I agree with you, Tom, mostly. However, about 10 years ago I bought an MFJ 259B. I thought when it said it measured impedance, it meant magnitude and angle. When I called them, they said NO. They thought impedance meant absolute magnitude. It was a great disappointment.

Within a few weeks, it became erratic at some frequencies. I bought other equipment to check it out and found that the 259B was pretty much lying to me.

It is now in my junk bin.

Don't ask me about the headphones I got from them.

Always a risk buying used ATUs. As noted earlier, it is easy enough to do permanent damage to a '949E with a 100W transmitter.

Re the loose nuts... so you got one that look like it is factory fresh. Loose nuts, nuts floating around loose in the case and loose lumps of solder are commonly reported in new product, mine was that way (a few blobs of solder and a spare nut).

Is it unfair to say that buying some MFJ products is a bit like buying an unfinished kit?

Now for something constructive, now that you have put the case back together.

Would you like the PEP meter function to work properly (instead of 'truly'). There is provision for a transistor and couple of related parts, <50c worth in all, that are not fitted to the board, presumably as a cost saving measure. If you populate those parts, the think WILL require 12V for the PEP function, but it will work properly, well pretty well.

Unfortunately, it is a half hour job to fit the parts post production.

Owen

Not new, no box and the unknowns dominate. I got no information from the
prior owner (SK). I also don't know for sure that it left MFJ without lock
washers. I don't know if it spent any time bouncing around in a car or
truck.

My remarks were not intended as an overarching expos� of MFJ gear.

It's been over a year.  Maybe now?

(It's not like I don't have the washers.  :-)

>   Hi Jeff,

Likewise. alt.internet.wireless appears to be dead. Oh well.
Thanks for posting the info on the coax cable in the MFJ-1800. I
couldn't find the applicable message with Google Groups.

>   I see MFJ now has a Bi-Quad 12dbi antenna.
>http://www.mfjenterprises.com/Product.php?productid=MFJ-1804
>If I send the the dimensions....

Ummm.... please don't do that.

> Just kidding!

Whew!

Interesting MFJ-1804 biquad antenna. In order to get 12dBi gain out
of something like that, it would either need to be 2 biquads and some
kind of power splitter, or one of those extended biquads as in:
<http://www.larsen-b.com/Article/201.html>
or the overkill version at:
<http://www.digdice.com/diy-wifi-antenna-double-dual-biquad-16-17-dbi/>
or maybe a biquad-yagi conglomeration:
<http://www.digdice.com/biquad-yagi-24ghz-antenna/>
Of course, MFJ supplies no specs, no manual, no dimensions, no test
results, no test procedures, no graphs, and no clue what's inside. For
$60, I would expect better, especially since I can buy something as
good or better for much less:
<http://www.l-com.com/item.aspx?id=21808> (3 element loop yagi)
<http://www.ebay.com/itm/170628411340>   (4 element patch ant)

Looks like MFJ has a line of 2.4Ghz products, that don't seem to be
easily found on the product listing pull-down.
<http://www.mfjenterprises.com/Product.php?productid=MFJ-1800>
<http://www.mfjenterprises.com/Product.php?productid=MFJ-1801>

I had a similar experience. I friend loaned me some monstrous MFJ antenna tuner, probably just to get it out of his crowded shack. I tried to characterize the tuner to see what it would do, and immediately ran into stability issues. I couldn't get consistent sweeps and measurements. I eventually beat on the case and noticed that the scope traces were moving. That was traced to numerous loose screws and to marginal solder connections. It took a while to get everything tightened down properly. That fixed the stability problem. Even fixed, it took me another month or so get convince my friend to take it back. I don't really need a kilowatt tuner for my 100w radio(s).

Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to
rec-radio-amateur-moderated-request@panix.com.

Look at SVXLINK. It's an open source package that runs on Linux (and possibly BSD) that does exactly that.

It includes support for remote receivers (with a voting option), remote transmitters, and an echolink server.

We plan to use it with hard wired internet links, but who knows, an 802.11 link could work. Unlike the US we are restricted to 100mW EIRP, so no gain antennas, etc, to make things work better.

Yes, I read it the email, it was able to get over it's seperation anxiety and move on. :-)

Seriously, it helped me fix the problem. I just never spent a lot of time
with it after that, someone offered me a Drake SPR-4, and I traded it.

This is the grounding of an antenna coax to the chassis of a tuner. The wrong
stuff in the wrong place would be a disaster. At least with lockwashers, I
know there will be a good contact.

Do you have a transmit ban on 802.11 channels in 4X too?

We as hams in the Netherlands are no longer allowed to transmit above
2400 MHz except to an amateur satellite.

There is a limit of 100mW EIRP for 2400-2450 mHz for terrestrial use, with a limit of 100W EIRP to satellites in the 2400-2402 mHz part of the band. This is from a document on the Ministry of Communicatons website, dated 1999. It has been unchanged except for the addition of 7.100-7.200 mHz so they never bothered to update it.

The difference between a 100mW limit and an outright ban in practice is very little IMHO.

For example, you can turn off encryption and use a WiFi device as a packet radio, or you can call CQ on your cordless phone. :-(

> I wonder how important matching is for a pure direction finding antenna,

I don't think it affects sensitivity, which is not really at a premium anyhow.

A gamma match seems to skew forward-max location a bit to one side, which matters if you're relying on accurate bearings from a distance, but overall it doesn't matter much - in some ways it's better to expect to spiral in on the fox a little anyhow, I reckon.

The gamma match also goes wonky if you put your hand on it, but I guess that's not surprising. many of the top competitors use them anyhow - we have a design that's easy to disassemble to put into a suitcase for air travel.

One of the guys built a much-enhanced version of the NEC software for the Mac, and he's automated it to automatically optimise (millions of individual runs with different combinations) a 7-element boom for 70cm, which is yielding very impressive DF results right across the band.

Ya, I have my doubts about the 12 dbi gain figure. I have built a few
biquads, (with your feed point correction), it has amazed me how easy
it is to make them work (at 2.4 Ghz), I always thought the short
wavelength would cause many dimensional errors. Yes, they work, what
does "work" mean :-)
I've settled on a flat panel antenna for my boat antenna
(15dbi manu. spec.) At one time I had a dish with biquad feed, but it
was to tight, when the wind blew or tide changed it would miss the target.
Do you believe the 20 dbi figure?

Just discovered a dinky 20m yagi. made from wooden dowel with an 8ft square section to connect the two ends, the electrical parts are simply wire where required.

Being 8ft across the ends and slightly more lengthwise to allow for a turning radius, it looks like it could fit in my loft. I already have a lightweight rotator that could handle that. I think it was supposed to be a caravan tv aerial originally.

To make things even lighter I wondered if I could use pvc conduit with alloy tape as the elements? Either way I think ist worth a go.

My problem is my rotator, it has twin core cable from its little remote, so theres no way to determine where Im pointing.
So thats my query, anyone any ideas how I can show something downstairs, while this is turning in the loft?

Best I could come up with is to use some sort of lighweight motor/gears arrangement to work a pointer, by splitting the feed cable in two and using one as a feed for that,perhaps that would work?

1) It stops at one point and must be reversed.
2) It cant turn continuously.
3 Dont know how real ones work at all.
4) No idea if a proper one can be jury rigged ro work here.

>does "work" mean :-)

For a given physical size antenna, high gain antennas imply narrow bandwidth and critical construction. On the other foot, low gain antennas, such as the biquad, is fairly broadband, and therefore not particularly critical to construct. What's fun is to attach the antenna to a reflection coefficient bridge or directional coupler,
<http://pe2er.nl/wifiswr/>
<http://www.qsl.net/n9zia/rlb/texscan.png>
<http://www.qsl.net/n9zia/rlb/>
sweep generator, and oscilloscope to look at the VSWR curve. Then try moving things around. On my crowded workbench, location of the antenna relative to the highly reflective test equipment make a huge difference. The changes do not really have a big effect on antenna operation, but they certainly present a different picture as compared to the nice clean curves on the data sheets.

>   Do you believe the 20 dbi figure?
>http://www.ebay.com/itm/20-DBi-2-4GHz-Wifi-Yagi-Antenna-RP-SMA-Router-Wifi-/110730734175?_trksid=p4340.m1374&_trkparms=algo%3DPI.WATCH%26its%3DC%252BS%26itu%3DUCC%26otn%3D15%26ps%3D63%26clkid%3D2473925749399603295

I guess you missed my previous rant on the subject. I bought two of those yagi antennas (for $6/ea incidentally) just to see what was wrong with them.
<http://802.11junk.com/jeffl/crud/wi-fi-yagi-that-sucks.jpg>
Notice the really crude dipole driven element hiding under the plastic. That isn't going to work. No balun, no matching, exposed coax wires, and offset from the center line too much. Some tests showed that it has more gain to the side than towards the front. I also suspect that the rather large size boom diameter was not considered in calculating the element lengths. A piece of total junk, but at the price, probably sells well (which is why I like the antenna biz).

The above yagi is apparently a cost reduced clone of a similar yagi that does have a proper feed and a more realistic gain claim. I think (not sure) that this is the one:
<http://www.ebay.com/itm/250847584296>
I have no idea if this one works any better.

This is a more reputable source:
<http://www.comtelcoantennas.com/yagi_1_8_2_4_ghz.htm>
Note the radically higher prices and the 14dBi gain for a 16 element yagi:
<http://www.comtelcoantennas.com/PDF%20Datasheets/Y422416.pdf>

In my experience, PVC conduit tends to sag if used for horizontal elements... it needs to be supported every few feet or it will "droop".

>My problem is my rotator, it has twin core cable from its little
>remote, so theres no way to determine where Im pointing.
>So thats my query, anyone any ideas how I can show something
>downstairs, while this is turning in the loft?

That depends a lot on just what sort of rotator it is, whether the remote is intended to have any sort of display, etc.

Some old-style TV rotators were intended to be "self-aligning" by means of a clutch... turn the knob all the way clockwise, wait until the antenna stops rotating, turn the knob all the way counter-clockwise, wait until it stops, and you now know that the antenna is certain to be all the way at one end of its travel (e.g. due northwards, if that's the way you originally mounted it) and you can rotate it back to any desired direction.

If worse comes to worst you may need to add some sort of extra readout sensors - e.g. a multi-turn potentiometer, linked to the rotating part of the mast through a belt or idler-pulley arrangement - and run an extra set of sensing wires down to your shack.

>Best I could come up with is to use some sort of lighweight
>motor/gears arrangement to work a pointer, by splitting the feed cable
>in two and using one as a feed for that,perhaps that would work?

Depends if the feed cable has a separate ground (braid) or is just the two leads.

I think we need more details on just how your rotator works (and is
wired) and how the antenna is wired up, to offer good advice.

The rotator is a pretty simple affair, the lead is bellwire, straight
two two core bellwire. It stops same place every time either way so
the internal gears ,must be doing something right.

My apologies though....I think Im in the wrong NG? I reinstalled my
reader and may have screwed that up a little, I noticed I could upload
pics so I tried that with a simple osc diagram, which refused to go.
I dont want the Mod thinking he had some incoming pornfest on the way,
my call is indeed my own verifiable callsign here in Scotland if you
need to verify.

Thanks

Thanks, Owen, but the measurement function is no big deal to me.

I already have several powered in-line meters that I'm _not_ using.

For pics, put them on a website and post the link here. Many do that. Easy to use is Picasa; others may be easier.

Powering the rotator usually involves applying 28 - 36 VAC. One side of the

AC is tied directly to two coils in the motor; the other end of those coils is tied to the other side of the AC, one directly and the other through a capacitor. Direction of rotation is established by which coil is fed directly.

I know of three ways to indicate the rotator's position. One uses a tapped resistor to send a portion of the applied voltage to the controller, which has a meter in it. It only indicates when power is applied (during actual rotation).

The second uses a make-break contact in the rotator to send a sequence of pulses to a spring-loaded stepper during rotation. It indicates the position with a mechnical pointer on the controller. Indicates always.

The third has a small motor in the controller, turning an indicator at (we hope) the same speed as the rotator. Indicates always.

If you can determine that your rotator uses one of these, maybe we can take you and your rotor to the next level.

There isn't a USENET moderator, per se, in this newsgroup.

However, many USENET providers do honor the "No binaries here!" charter for this group, and won't pass along articles that contain them.

Now... as to a solution to your problem. One might be the approach I think you were thinking of - use one lead in the bellwire for power, the other for a readout signal, and use your building's grounding system as the return for both. This would probably work, but I don't recommend it... mains-wiring earthing should really be used only for safety purposes and should never carry currents. In the event of a wiring fault, you might find your antenna-rotor system carrying some very high fault currents (many amperes) and could expose yourself to shock and equipment damage.

One simple approach would require no new equipment or wiring at all, except a wristwatch. Simply figure out how long it takes your rotator to go all the way from one end of its travel to the other. In order to aim the antenna to a specific direction, rotate it all the way one way (maximum turn time) and then rotate it back for a variable amount of time based on the direction you want it to point. As long as the rotator "clutch" can stand to spin against the stop for a full rotation-time, this should be safe enough. If the rotator doesn't have a clutch - if you're actually "stalling" the motor when it hits the end-stop - then you shouldn't keep running it past this point (might overheat the motor) and should stop rotating when the motor stalls and the current jumps upwards.

There are plenty of fancier approach which could be tried, which would carry both DC power to the rotator, and some sort of measurement and/or control signal, over the same cable. The latter might be carried as an audio tone, for instance.

>I'm curious, did you do any measurement and testing with an analyzer, etc., or
>are all the figures simply calculated estimates?

There are no affordable "analyzers" that work at 2.4Ghz. I also have not owned, or plan to own an MFJ-1800 antenna. The physical measurements were done by a friend that owns this antenna and was wondering why it didn't provide anywhere near the gain promised (as compared to a commercial panel antenna).

Incidentally, I recently purchased a pair of totally misdesigned 2.4Ghz yagi's on eBay for about $8/ea.
<http://802.11junk.com/jeffl/crud/wi-fi-yagi-that-sucks.jpg>
Note the crude driven element, exposed coax conductors, and lack of a balun. What happened was that this was a cheap clone of another similar antenna, which did provide all the required matching circuitry. This vendor decided it was too much trouble to copy the matching network and balun, so he just left it out. It has more gain to the sides of the yagi, than in front.

>Has anyone confirmed what the piece is that connects the driven element with the
>coax connector that looks to be a short piece of coax covered in heat shrink?
>Has anything been found or measured hiding under the heat shrink?

There's a ferrite bead under the shrink tube. If you can find a ferrite material that actually works at 2.4GHz, it might pretend to do something useful. However, no way is it going to provide a 4:1 impedance transformation.

>I realize we can all assume the antenna impedance is 50 ohms, but is it actually
>stated in any of the specifications from MFJ? I didn't see any mention of
>impedance specification at all for this antenna, but I could only find
>information on the web page at the link you provided as well as in the pdf file
>of the instructions for the MFJ-1800. The instructions are rather sparse.

Good point. One can assume that if it uses a 50 ohm coax pigtail, a 50 ohm N connector, and is designed to connect to a wireless device that presents 50 ohms, it just might need to be a 50 ohm antenna.

>Thanks for taking the time to provide details.

Yeah, I've done dumber things. There were several long discussion on the topic in various newsgroups. The discussions inspired my burning several evenings modeling the antenna:
<http://groups.google.com/group/alt.internet.wireless/browse_thread/thread/c891c0060ec92257/>

The Avago HSMS-2820 detector diodes in the MFJ-259 tend to blow up. It
apparently doesn't take much RF to do the damage. Suggest you buy
some spares from Digikey (516-1817-1-ND) or Mouser. Ten for about
$0.60/ea.

(repost updated)
All started because I could not get the PVC tubing which the many
internet sites propose. The plumber shops where I live can only supply
heavy massive material suited as killing weapon in the hands of a
desperate fox transmitter hunter.

So I had to look for an alternative design and that lead me
to the aluminium boom with the movable slider.

With the PVC tubes it should be possible to make the middle "T"
moveable, or not? Would have to drill through the T with
a larger diameter wood-drill.
http://tinyurl.com/3vygo9f

I am here now:
https://sites.google.com/site/tapemeasureantenna/
This allows for future changes, updates and additions.

The old stuff is still there:
http://img839.imageshack.us/img839/1452/tapemeasurefoxhuntyagi.pdf

What's missing is a list of ready-to-build recipes.
Am still struggling with the tape-measure correction factors
for the antenna simulator (4nec2)
Anybody having already tried simulating tape measure antennas?

3 element Tape measure direction finding antennas are a bit larger
than their 2 element competitors like the MAY1000
http://www.rfparts.com/diamond/MAY1000.html
A simple two element ARDF antenna must be carefully adjusted
in element spacing, else it will be totally worthless. This often
applies to the portable HB9CV antennas from the junk box
which are being used off their design frequency.
I cannot imagine running through underbrush thicket with the MAY1000.
It will quickly fold into it's sales package size :-)

w.

Regards,
w.

Not tape measures, but I have done stamped sheet metal, which is
somewhat similar. See the plots at:
<http://802.11junk.com/jeffl/antennas/mfj1800/index.html>
The NEC2 deck is under:
<http://802.11junk.com/jeffl/antennas/mfj1800/slides/mfj-1800.html>

The problem is that the common "wire" rod antenna elements aren't
close enough. So, I had to use the actual dimensions from the sheet
metal. You'll probably need to do the same, with the added
complication of including the arc in the cross section. It's not as
horrible as it might seem as all your elements are the same cross
section. Use the "Geometry Builder" program that comes with 4NEC2.

>I cannot imagine running through underbrush thicket with the MAY1000.
>It will quickly fold into it's sales package size :-)

Have you considered an inflatable version?

<http://www.scouting.org/filestore/jota/pdf/TURNER.pdf>
Hmmm.... they use a WB2HOL tape measure antenna.

They don't blow up, they burn up. Always keep the input grounded (I have
a banana plug ground I use when storing my 259B) until you are ready to
use it. Short the center conductor of the DUT to ground immediately
before connecting to the 259B. Do not transmit from any nearby antennas.

A tin can is too small. I think you mean a coffee can.
In my never humble opinion, the cantenna sucks, but works tolerably
well for illuminating a parabolic dish.

Here's a model of the common coffee can antenna.
<http://802.11junk.com/jeffl/antennas/coffee2400/>
Notice the boresight error caused by the off center probe feed. 9.8dBi
gain, but there's a problem with my model somewhere. The average gain
test shows 1.54 indicating that the calculated gain is 1.88dB too
optimistic. The real gain is more like 8dBi. I can do that with a
biquad.

The cantenna also has a problem with calculating the probe feed
length. Where do you measure to? Starting from the tip, do you

measure to where the insulation stops on the N connector? To the metal sleeve around the insulation? To the N connector base? Or perhaps to the tin can itself? The error is not trivial. 1/4 wave at the band edges are 3.02cm and 3.12cm. Assuming you want to land somewhere between these limits, the cut error is:

   3.12cm - 3.02cm = 0.10cm = +/-0.5mm

That's also possibly one of the reasons the original designer used a conical probe feed. More bandwidth means any error has a smaller effect.

I won't mention that the bottom of the can is rarely flat, making that distance also a bit tricky to get right. Never mind that there's way to adjust anything other than the length of the wire probe and it's bend angle.

About 3 years ago, I was blessed with a friend who built about 6 assorted cantennas, but had no reliable way to tune or test them. I stupidly volunteered. Most of them were resonant at about 1.8GHz. Chop, cut, hack, solder, and they're now on 2.4Ghz. Measuring the gain, none of them came close to what was expected. My indoor antenna test range leaves much to be desired, but my transfer standard antenna is accurate to +/-0.5dB gain.

The reason that the cantenna is such a "killer" antenna is that literally *ANY* external antenna is an improvement over the stock chip, PIFA, or rubber ducky collinear antenna found in most Wi-Fi contrivances. You can even build one incorrectly and it will work better than the stock antenna. For your amusement, here's a proper biquad:
<http://802.11junk.com/jeffl/antennas/Biquad/index.html>
and by the way far too many web pages suggest it should be built:
<http://802.11junk.com/jeffl/antennas/biquad-junk/index.html>
The good antenna has a 50 ohm coax feed between the reflector and the bow tie. The loser has a pair of wires, at some unknown impedance, in the same place. Amazingly, it has almost the same gain, despite the high VSWR.

Killer antenna, my posterior...

Incidentally, I once scribbled a spreadsheet that allegedly generates
an NEC2 card for a cantenna, given the can dimensions.
<http://802.11junk.com/jeffl/rf-calc/Coffee-can05.xls>
In theory, you should be able to cut-n-paste the section in blue, save
it as filename.nec, and feed it to 4NEC2 as can feed. It was
originally intended for parabolic dish feeds, but can be used for a
stand alone wi-fi antenna. Unfortunately, it's not ready for prime
time and has some errors. It's been so long since I threw it

together, that I don't even remember what was broken. Caveat Emptor.

Nope. That's on how to build a cantenna. What I'm doing is taking a given size can, and generating an NEC2 deck suitable for modeling the design. There's nothing on that web page about modeling. For that matter, there are no test results and no cool looking plots. You could build the cantenna according to the instructions, and never really know what you've got, or what to expect.

Incidentally, I like the various photos of testing the cantenna on a camera tripod. My guess is that the tripod is about 3ft off the ground. Quiz: What's the maximum distance you can go at 2.4Ghz with both ends 4ft off the ground, before the Fresnel Zone hits the ground?
<http://www.terabeam.com/support/calculations/fresnel-zone.php>
Plugging in various guess in the range, I get 0.025 miles or 132 ft.
Several of the antenna tests (can't find the link again) were longer.
Oh well.

Good tip, Jeff. One thing that would be cheap insurance and make for
less units shipped back is a dummy load to put on the antenna socket. I
made one up for cheap.

The model is at:

<http://802.11junk.com/jeffl/antennas/coffee2400/index.html>
Note the 5 degree boresight error at:
<http://802.11junk.com/jeffl/antennas/coffee2400/slides/horiz-01.html>
That's not too horrible considering the 65 degree -3dB beamwidth.

I've seen several antenna with proper launchers. Here's one:
<http://www.seattlewireless.net/CookieCantenna>
The funnel will add about 4-5dB of gain depending on size. That begs the question whether it would be easier to just built a horn antenna and be done with it. The horn has more gain, easier to build, flat surface for easier connector mounting, tunable back end of waveguide, and potentially more portable:
<http://www.wired.com/culture/lifestyle/multimedia/2004/08/64440>
<http://www.brest-wireless.net/gallery/AntenneCornet>
<http://www.seattlewireless.net/CardboardHorn>

Also, I forgot to mumble something about the N connector mounting screws and nuts projecting into the waveguide. Not a good idea as those will have some effect. The screw heads should be on the inside of the can, with the nuts and uncut threads on the outside. It will look horrible but it will work better. Copper pop-rivets would probably be best.

I have a 2.4 GHz TV downconverter built into a coffee can.  It was
tough to get a good picture, so I made a horn for it, using hardware
cloth.  The horn is about three feet long and about three feet across
at the open end.  I never made any quantitative measurements of the
increased signal at Channel 3 (the nominal output) but the reduction
in snow was considerable.

Hi. I foxhunt regularly with the Melbourne ARDF community, and we have the design of 2m sniffer antennas down to a fine art.

The best material for the shaft is 12mm square or u-channel aluminium.

The common antenna element length and spacing recommended with the tape-measure antenna is wrong - very wrong. For a start, the lengths vary by too much (in the hope of a wider effective bandwidth), and the reflector is too close to the driven, the director too far away. This causes large rear side lobes, which makes sniffing incredibly frustrating.

For effective sniffing, you *don't* want maximum F/B ratio, and you don't want maximum gain - what you want is a cardioid pattern with just one lobe - the front one. Anything else will give you a bum steer.

The best pattern we've found so far is the VK3VT beam: <http://www.vk3vt.net/VTbeam.html>. Most of the recent ones use a gamma match instead of the one shown.

We build this using elements made up from 3mm fiberglass rod and co-ax braid, covered by heatshrink. The element goes through a short copper tube before the heatshrink goes on.

These elements are sufficiently stiff to keep their shape, but whippy enough to run with through a tree.

Clifford Heath.

I just ground the center of the SO-239 with a common Pomona banana plug.
A 50 Ohm load isn't necessary.

Dummy load or short, it doesn't matter. It's probably not RF that's
killing the diodes.

Schematic of the MFJ-259B at:
<http://www.dk3red.homepage.t-online.de/en/s8a.htm>

I took the liberty of somewhat cleaning up the RF input section at:
<http://802.11junk.com/jeffl/crud/MFJ-259B-RF-section.jpg>
Note that diodes D2 and D3 are directly connected to the center pin of
the RF connector. These are the two that usually blow up, not the
others. Oddly, I'm finding both blown, never a single diode. My
guess(tm) is that they're being killed by a blast of static
electricity, not RF.

Notice the lack of a high value bleeder resistor on the antenna
connector. This bleeder resistor is standard on anything connected to
an antenna that might build up a static charge. Every radio that I
designed has this resitor. It doesn't take much static electricity to
blow an unprotected diode. Just connect the MFJ-259b to an ungrounded
antenna in a wind on a low humidity day, or just touching the antenna
while sliding across a plastic car seat. When I replace the diodes,
I've been adding a 100Kohm resistor from the junction of D2/D3 to
ground, which hopefully will help. So far, no returns.

Hmmm.. while you might not be able to buy an analyzer, that doesn't mean that you couldn't have done the measurement by other means. A power meter (perhaps an eval board for one of the analog devices parts)? Maybe even using a WiFi card as a field strength meter at a little distance away, and then using an adjustable stub tuner (e.g. microstripline on a PC board. (or one of those "check your microwave oven for leakage" meters from radio shack)

Sure, it's not as nice as that VNA from Anritsu or Agilent, but people have been making microwave impedance measurements for decades with pretty primitive gear.

Building a directional coupler in microstripline is a cookbook endeavor.
  An hour with some copper clad board and a razor blade would do. If you happen to have some copper foil tape around, it's even easier.

An impedance measuring system along the lines of the "3 meter" technique (where you have a known L or C in series) is a possibility.

Not to mention that there are a lot of folks on this list who DO have access to suitable analyzers.

So Renee's question was pretty reasonable.

What happened was that this was a cheap clone of another similar antenna, which did provide all the required matching circuitry. This vendor decided it was too much trouble to copy the matching network and balun, so he just left it out. It has more gain to the sides of the yagi, than in front.

Fascinating... especially since the matching network wouldn't normally have any effect on the pattern. Balun/Choke having an effect, I could see (coupling to the feedline screws up the pattern).

>
>> Has anyone confirmed what the piece is that connects the driven element with the coax connector that looks to be a short piece of coax covered in heat shrink?

> There's a ferrite bead under the shrink tube. If you can find a ferrite material that actually works at 2.4GHz, it might pretend to do something useful. However, no way is it going to provide a 4:1 impedance transformation.

2.4 GHz is 12 cm wavelength

4-6cm of transmission line is a good fraction of a wavelength. How do you know it's not 3/4 lambda of 75 or 92 ohm line, or something like that. (1/4 wavelength of 75 ohms would transform 200 ohms to about 30 ohms, for instance)

I've worked with enough UHF and microwave antennas with weird funky feedpoint things to not trust in first impressions. There could be all sorts of parasitics that help the situation out, and they're tough to model accurately (you're certainly not going to do it with NEC, for instance.. I'd trust NEC for the feedpoint impedance without matching/balun/stubs..)

Yeah, it's probably not a nice 1:1 match over the entire band, but then, most antennas aren't. It just has to be "good enough" and in that business, the loss in the feedline probably dominates anyway. Figure 3 dB of loss in the feedline, and you get a 6B improvement in return loss.

The model you have shows a beamwidth around 30 degrees (H) and 28 degrees (V).. that's a directivity around 16 dBi

4NEC2 is giving you 14dB gain.. that's moderately consistent, although 2 dB is something I'd want to figure why the difference. I'd want to figure out why 2dB different, especially since you didn't put resistive loading into your model, which, at 2.4GHz *will* make the match better

MFJ claims 15dBi, and that is also consistent with your model and the back of the envelope from the pattern.

Nope.. not if the feedline is a couple dB loss (which wouldn't be unusual for a laptop pigtail using RG-174 or smaller).. All they really care about in this kind of application is the directivity.

After all, how many ham antennas for HF have a PL-259/SO-239 "UHF" connector on them. I wouldn't take the fact that it has a 50 ohm connector as indicating anything other than it's a common connector that people are likely to have mating connectors for.

75 ohm BNC, Ns, etc exist, but how many people use them on dipoles (which have 72 ohm impedance)... nahh. they just use a 50 ohm cable, UHF connectors, and are done with it.

If they used 75 ohm coax on this antenna, and it's close to a multiple of 1/4 wavelength, then the match at the N connector is probably not a lot worse than using 50 ohm coax on a dipole.

Well, not having the antenna prevented me from doing much. If I had

the antenna, I would have connected it to a home made reflection coefficient bridge and my Wiltron 610D sweeper. I also have some directional couplers, but all my detectors are currently blown.
<http://802.11junk.com/jeffl/pics/home/slides/BL-shop6.html>
(Right now, there's a chain saw torn apart on the bench). Either bridge or coupler would have shown high VSWR for the antenna.

Incidentally, I don't consider it my job to supply test data for MFJ. MFJ should run the tests and post both the procedures and test results.

While it's a good thing to verify models with actual measurements, in this case, just creating the model burned all my spare time for about a week. I don't think I would have had time to do anything more than a rough sanity check type of test.

>A power
>meter (perhaps an eval board for one of the analog devices parts)?

I have several microwave oven testers. They will barely detect RF from an access point. Basically, they're just a diode detector, with no RF gain. I wouldn't expect much from them:
<http://802.11junk.com/jeffl/pics/Microwave%20Leakage%20Detector/>
The detector diode is on the far left.

I do have an indoor antenna range of sorts. It's full of reflections, but is good enough for measuring gain using a reference antenna. In this case, I had a patch antenna and a biquad antenna tested in an anechoic chamber and obtained fairly accurate gain curves. My guess is that I can measure gain at 2.4Ghz to +/-2dB. Not great, but better than guesswork.

>Sure, it's not as nice as that VNA from Anritsu or Agilent, but people
>have been making microwave impedance measurements for decades with

I still have several slotted lines buried somewhere.

>Building a directional coupler in microstripline is a cookbook endeavor.
> An hour with some copper clad board and a razor blade would do. If
>you happen to have some copper foil tape around, it's even easier.

Yep, I've done that. On a good day, I'll get 20dB directivity, which isn't so great.
<http://www.qsl.net/n9zia/24swr/index.html>
I prefer a reflection coefficient bridge, as in:
<http://pe2er.nl/wifiswr/>
I've built several of these. It won't tell you whether the antenna is inductive or cazapitive, but will supply the VSWR (actually, the

reflection coefficient).

>An impedance measuring system along the lines of the "3 meter" technique
>(where you have a known L or C in series) is a possibility.

Pardon my ignorance, but what's that?

>Not to mention that there are a lot of folks on this list who DO have
>access to suitable analyzers.

Great. Let them borrow and MFJ-1800 antenna and run their own tests.
>So Renee's question was pretty reasonable.

True. I should have tested my model to verify my allegations. Perhaps
I should also do indoor/outdoor tests, in various environmental
situations, in the presence of interference, and with a side by side
comparison with other antennas. Yeah, that would be great, but I
don't have that much time (or money). I threw together an NEC2 model
that suggested that the antenna is mis-designed and left it there.

>> Incidentally, I recently purchased a pair of totally misdesigned

I didn't include the feedline in my model, which due to the lack of a
balun (I don't consider the ferrite bead to be a balun due to the high
frequency) will radiate and produce weird patterns. Never mind the
fairly large lengths of exposed conductors at both ends of the coax
cable. I'm not sure exactly what a 200 ohm antenna in a 50 ohm system
will do. 300 ohms in a 50 ohm system is a 6:1 VSWR and a 3.1 dB
mismatch loss. So what if we loose half the power in the mismatch.

The owner of the antenna measured the coax cable dimensions. From that, we determined that it was 50 ohms coax. I have the numbers buried in email correspondence somewhere. I'll see if I can find them. Digging.... Nothing yet, but I did find one more photo:
<http://802.11junk.com/jeffl/MFJ-1800/>
While it's difficult to transfer dimensions from the photos, the coax cable even looks like a 50 ohm cable. Not the thick center conductor, which makes 92 ohms improbable, and 75 ohms unlikely. You can see the ferrite beads through the stink tube.

>I've worked with enough UHF and microwave antennas with weird funky
>feedpoint things to not trust in first impressions. There could be all

Well, that's what my model did. The characteristic impedance of the model is set to 200 ohms at the folded dipole. No matching network involved. See:
<http://802.11junk.com/jeffl/antennas/mfj1800/slides/VSWR.html>
and note the 200 ohms in the upper left of the VSWR graph.

>Yeah, it's probably not a nice 1:1 match over the entire band, but then,
>most antennas aren't.

Look again at the graphs.
<http://802.11junk.com/jeffl/antennas/mfj1800/slides/VSWR.html>
It's absolutely gorgeous across the band. Less than 1.3:1 from 2400 to 2483.5. I would also have expected a much more narrow band antenna and was very surprised at the wide bandwidth. That's not normal for a high gain yagi.

>It just has to be "good enough" and in that
>business, the loss in the feedline probably dominates anyway. Figure 3
>dB of loss in the feedline, and you get a 6B improvement in return loss.

Yep. That's why I measure VSWR at the antenna, not the source. I like to use LMR-400 with 6.6dB loss per 100ft. 3dB loss would be about 50 ft of coax cable, which is MUCH longer than I would use at 2.4GHz. Also, I'm partial to putting the radio next to the antenna, which reduces coax losses to nearly zero.

>The model you have shows a beamwidth around 30 degrees (H) and 28
>degrees (V).. that's a directivity around 16 dBi

Yep. For the benefit of those trying to follow all this, see the

numbers in red at the right:
<http://802.11junk.com/jeffl/antennas/mfj1800/slides/Horiz.html>
Incidentally, notice the asymmetrical pattern, caused by the off
center line position of the copper folded dipole driven element.

>4NEC2 is giving you 14dB gain.. that's moderately consistent, although 2
>dB is something I'd want to figure why the difference.

The 2dB is from the -2dB gain in the reverse direction (180 deg).
14dB forward gain. -2dB reverse gain.   14 - (-2) = 16dB directivity.
I don't see a problem.

>I'd want to
>figure out why 2dB different, especially since you didn't put resistive
>loading into your model, which, at 2.4GHz *will* make the match better

Ummm... why would I need a load? I'm only interested in what the
antenna looks like to whatever I connect to the terminals. If I
included the generator source impedance in the model, I would have to
also include the generator output impedance characteristics,
connecting cables, and possibly some manner of 4:1 xformer.

>MFJ claims 15dBi, and that is also consistent with your model and the
>back of the envelope from the pattern.

Close enough. When in doubt, always round up to make the numbers look
better.

Maybe. Using coax loss to improve VSWR is an old trick. Whether it's
being done intentionally is debatable. I prefer to assume that if all
the major components are 50 ohms, then perhaps the antenna should also
be 50 ohms.

>After all, how many ham antennas for HF have a PL-259/SO-239 "UHF"
>connector on them.

Too many. However, HF antennas are not as critical to construction and component differences as microwave antennas. What hams get away with building HF antennas, would be doom and disaster at microwave frequencies. You also don't see UHF connectors and banana jacks at UHF frequencies.

>I wouldn't take the fact that it has a 50 ohm
>connector as indicating anything other than it's a common connector that
>people are likely to have mating connectors for.

Ok, I'll conceded that there's a possibility that there's some matching magic going on behind the curtains, that's not visible to mere mortals. Lacking the necessary insight, I prefer to judge based on what I can see, feel, touch, understand, and test.

>75 ohm BNC, Ns, etc exist, but how many people use them on dipoles
>(which have 72 ohm impedance)... nahh. they just use a 50 ohm cable, UHF
>connectors, and are done with it.

Most of the feed lines to my roof are 75 ohm CATV rigid cable. Also, plenty of 75 ohm RG-6a/u. Worst case VSWR for doing this is 1.5:1. The tiny mismatch loss for this arrangement is more than compensated for the lower coax loss of 75 ohm coax, compared to similar sized 50 ohm coax.
<http://www.qsl.net/n9zia/wireless/75_ohm_hardline.html>

>If they used 75 ohm coax on this antenna, and it's close to a multiple
>of 1/4 wavelength, then the match at the N connector is probably not a
>lot worse than using 50 ohm coax on a dipole.

The antenna impedance (by my model) is between 200-300 ohms. To use a 1/4 wave section to match that to 50 ohms, the coax would need to be:
   Zo = (Zout * Zin)^0.5
   Zo = (200 * 50)^0.5 = 100 ohms
93 ohm RG-62/u would probably be close enough. However, the coax cable in the photo is certainly not 93 ohms (judging by the fat center conductor).

Yup, and pretty true.  Most hams don't know crap or how to measure it.
```

Did you exceed the ratings of the device?

Silly question, because you probably didn't know the load you were
trying to match.

tom

You wouldn't be the first person to damage a '300W ATU' witha
transmitter of less than 300W.

The point is that the power ratings on ATUs (and lots of other accessories, eg baluns) are extravagant giving that they are not explicitly conditioned on some operating parameters.

I expect that an MFJ949E will handle 300W from 160m to 10m if matched into a 50 ohm load... but does that make such a statement a worthwhile specification for the thing. No, of course not because if you had 50 ohm load you don't need the ATU.

Do the specifications for this or any ATU state X kW at any load impedance (any magnitude, any phase)... not in my experience.

I have heard people brag that "my ATU is so good, I can get VSWR=1 with not antenna attached". Ok, that is a recipe for damaging the ATU, and if it was an MFJ949E and its voltage balun was in circuit, that would be at risk.

I wrote some notes at
http://www.vk1od.net/transmissionline/aev/index.htm about high voltage damage to ATUs, and realise that not only may it cause flashovers, but high voltage causes highest dissipation in voltage baluns.

Owen

Do you think the matching affects the cardioid or F/B pattern?
So far I have neglected any influence from that.

With the YAGICAD optimizer I could not come to a positive end.
This program finds 100 different "optimums" therefore
I turned to 4nec2 now.
The patterns which YAGICAD calculates look good to me.
When I compare the F/B patterns, of course the 4nec2 has a more
detailed "resolution" showing minor side lobes where YAGICAD
is just approximating.

I wonder how important matching is for a pure
direction finding antenna, methinks rather it should not.
Only the coax cable currents are not considered
in the simulator diagrams, there might be an influence.
Therefore matching is important :-)

Thank you for the vk3vt link.

Xref: g2news2.google.com rec.radio.amateur.antenna:24199

I was looking at cheap HT's last night on eBay and I found several vendors selling duplexers for repeater use. They sell for about $60 each.

They are 6 cavity (three transmit, three receive) and the closest they can go on VHF is 3.5mHz.

Doing a web search I find they are not very good (what did you expect?) but with a good front end they will work ok.

My problem is not only one of money (don't tell me to not waste my money and buy a good, one, I can't afford it), but my 2m band is only 144-146 mHz, and the repeater portion is really just 145-146. I'm also limited to 20w output.

So my question is anyone familar with them? Is it possible to take one and convert it to a 6 cavity input filter? For example, I could put the input on one side my yard and the output on the other, about 30 feet apart.

For example, if the input of the repeater was 145.600, could I have them both tuned to 145.600 and connect the input of the receiver to one set of cavities, the antenna to the other and leave the antenna connection untouched, effectively placing them in series?

Thanks in advance,

Geoff.

No. There are two sides, one of them for the high frequency and the
other for the low frequency. The filter response is such that it passes
on one frequency and notches on the other.

Ok thanks. Note that they are tunable anywhere in the 136-17? range.

Assuming the pass side is set to pass 145.600 (the input) and the notch
side is set to notch out 145.000 (the output) and they are connected in
series, would that work?

Geoff.

It is not a pass side and a notch side. Both sides are pass/notch.

But on one side the pass freq is above the notch freq, and on the
other side the pass freq is below the notch freq.

On the Chinese duplexers you have found, the Q is probably not high
enough to tune the pass and notch to frequencies 600 kHz apart.

He is wondering if something can be modified. He wants a half-duplex
radio with a 600 kHz split, on a common antenna. The duplexer he is
looking at has a 5 MHz offset. He wants to know if it can be
re-configured for ham with a much smaller offset.

> accomplish.

Take two radios, two j-poles and a lot of coax and make a repeater.
Obviously I will need some sort of controller in between but that's
irrelevant.

I want to place one J-pole (or similar antenna) at one corner of my garden,
and another at the other one (10 meters apart).

One will be used to receive a signal, the other to relay it. They both
will be somewhere on the 144-146mHz band, with the output being a few watts

with a max of 20.

Besides the distance, I was looking for a cheap way of not having
the transmitted signal block the receiver. The duplexer in question
is rated at 75dB isolation with a 3.5mHz split, I can only have .6 mHz.

What I was wondering is that since at a .6mHz split, the isolation will
be a lot less, can I somehow combine the two sides to make a better
filter?

Thanks,

Geoff.

There are calculators that will predict the isolation. At 20 watts
(+43dBm), with a broadband synthesizer noise level at about -30dBm,
and an RX sensitivity of about -106dBm, you'll need at least 76dB of
TX-RX isolation. The little cavities have too wide a notch (i.e. low
Q) and will attentuate the RX signal and smoke the TX signal at 0.6Mhz
spacing. Seperating the antennas won't solve that problem. If you
try to get sufficient isolation using vertically isolated antennas,
you might get sufficient isolation, but the Q of the notch filters
will still kill the signal both ways.

Vertical antenna isolation:
<http://awapps.commscope.com/products/bsa/_calculators/qvisolation.asp>
Horizontal antenna isolation:
<http://awapps.commscope.com/products/bsa/_calculators/qhisolation.asp>

>For example, if the input of the repeater was 145.600, could I have them
>both tuned to 145.600 and connect the input of the receiver to one
>set of cavities, the antenna to the other and leave the antenna connection
>untouched, effectively placing them in series?

Nope. Not enough Q (too wide a notch).
  Bigger cavities = higher Q.
  More cavities = deeper notch and therefore more isolation.

Quiz: The Q of given cavity is 1000. If I critically couple 2 such
cavities in series, what is the resultant Q? 10 such cavities? etc?

Answer: 1000 in all cases. The 3dB bandwidth does not change when
tuned circuits are critically coupled.

Read the specs on the eBay web page. For example:
<http://www.ebay.com/itm/110460354111>
  "Minimum Tx and Rx frequency difference: VHF 3.5Mhz"
That's not going to work with 0.6MHz spacing on the 2m ham band.

This is what a proper (Phelps-Dodge) 2m duplexer looks like:
<http://www.LearnByDestroying.com/k6bj/K6BJ%20Repeater/slides/2m%20duplexer2.html>
Note the much large size cavities.

Retch.

>I want to place one J-pole (or similar antenna) at one corner of my garden,
>and another at the other one (10 meters apart).

Plugging into:
<http://awapps.commscope.com/products/bsa/_calculators/qhisolation.asp>
I get about 30dB isolation (assuming 2dBi antenna gains).
The synthesizer noise belching from your xmitter is maybe -60dB down
from the +43dBm xmit carrier. That puts the noise level at -17dBm at
the receive antenna. Your receiver sensitivity is probably -106dBm,
which means you need about 90dB of isolation. The antenna spacing
will provide 30dB of that. You cavities are suppose to provide the
remaining 60dB of isolation. That's not going to happen with tiny
mobile duplexer cavities.

Hint1: You'll be close with vertical antenna isolation.
Hint2: Some radios have quite a bit of synthesizer noise, much of
which will be on your repeater receive frequency. This is why some
repeaters still use crystal oscillators instead of synthesizers.

>One will be used to receive a signal, the other to relay it. They both
>will be somewhere on the 144-146mHz band, with the output being a few watts

Somewhere? Duplexers are usually bench tuned to some specific
frequency. It's not a trivial exercise and requires some expenditures
in time and equipment. You can't easily move in frequency.

>Besides the distance, I was looking for a cheap way of not having

>filter?

You can't improve things by simply adding more cavities. All you'll
do is add more loss:
  Bigger cavities = higher Q and therefore closer frequency spacing.
  More cavities = deeper notch and therefore more isolation.

You should have stopped writing at the first thought. CHOKING is supremely important, and is a benefit found in good matching design. Choking can be achieved without matching, however. And choking will be needed at least at the feed point, and again a quarterwave down the line.

Why? Don't you make experimental stuff? I did not say it was a permanent repeater, it's actually a test bed for some repeater/internet linking systems we are trying out.

Budget is zero, but I can swing a roll of rg-6 and maybe a $60 duplexer if I don't buy anything else (radio/computer related) that month.

OK, thanks.

> Hint1: You'll be close with vertical antenna isolation.

Explain, do you mean just the distance if they are both vertical, or
the distance AND one is vertical and the other horizontal?

Also almost irrelevant. The radios wll be what I have, HTX-202s or what
I can scrounge (TBD). I'd love to get my hands on 2 channel Maxtracs
or similar radios out of taxis, but the people sitting on piles of them are
much more interesting in refurbishing and enhancing them than selling them
cheaply or giving them away.

I'd be very happy with ones that receive only or have blown finals that I
can get 2w or so out of.

I know, but I don't have a "pair" yet. I'm not even sure there are any
available or a test one. So why be specific when I don't have that information
yet, and why wait for it to ask a technical question, which will have
the same answer no matter which frequencies I use?

>Why? Don't you make experimental stuff?

I don't like J-pole antennas. I've also built too many repeaters in the past to know that they can't just be thrown together from available parts. One of my friends learned that expensive lesson with his 2m repeater. He started with two ham transceivers, went to two Maxtrac radios, and finally to a GE MSTR II. Duplexers went from 4 cavity junk, to a 6 cavity monster.

>I did not say it was a permanent
>repeater, it's actually a test bed for some repeater/internet linking

Sounds interesting. Plan on everything costing at least 4 times what's predicted, and for things to take perhaps 4 times as long. Unplanned repairs and "tweaks" should double the required time.

>Budget is zero, but I can swing a roll of rg-6 and maybe a $60 duplexer
>if I don't buy anything else (radio/computer related) that month.

Initial budget can be zero. Just plan on a replacement budget equal to the price of a proper repeater.

How's this for an expensive mistake?
<http://802.11junk.com/jeffl/K6BJ-MSF5000/>
I've burned about $800 on this mess and it's still not on the air. Wanna guess what went wrong? (Hint: it involves the internal duplexer).

>><http://awapps.commscope.com/products/bsa/_calculators/qhisolation.asp>

>> Hint1: You'll be close with vertical antenna isolation.
>
>Explain, do you mean just the distance if they are both vertical, or
>the distance AND one is vertical and the other horizontal?

Assuming vertically polarized monopole antennas, vertical isolation is from tip of one antenna to the tip of the other antenna. Horizontal isolation is just the horizontal spacing. If they're seperated both vertically and horizontally, then there's a problem. You only need to be offset horizontally slightly, for the antennas to couple. I ran into this problem when I tried to put two vertically seperated antennas on opposite sides of a tower. The isolation was better then they were directly in line with each other, on the same side of the tower. Incidentally, mounting one antenna upside down offers additional distance and improved isolation.

>I can scrounge (TBD).

Retch 2.0. Radio Shock HTX-202 handhelds tend to stick on the air with low battery voltage. The receivers are also easily overloaded. We have the remaining few HTX-202 radios used for APRS WX packet. I would love to replace them, but nobody (including me) want's to spend the time.

>I'd love to get my hands on 2 channel Maxtracs

>or similar radios out of taxis, but the people sitting on piles of them are
>much more interesting in refurbishing and enhancing them than selling them

Patience. On Jan 1, 2013, everything in the US is suppose to go
narrow band. There should be tons of cheap radios available on eBay
and from public safety outlets.

>I'd be very happy with ones that receive only or have blown finals that I
>can get 2w or so out of.

Make sure you get the ones with the 16 pin accessory connector. Many
of the Maxtrac's on eBay are actually cobbled together Radius or M120
radios, with odd boards and strange firmware. Caveat emptor.

>I know, but I don't have a "pair" yet. I'm not even sure there are any
>available or a test one. So why be specific when I don't have that information
>yet, and why wait for it to ask a technical question, which will have
>the same answer no matter which frequencies I use?

Careful. Some repeater frequencies are a problem. For example,
146.760 is on the 41st harmonic of the common 3.579545MHz clock osc
frequency. No problem at the repeater, but it will drive the users
nuts.

If co-located with other radios, be sure to do an intermodulation
study.
<http://www3.telus.net/PassiveRF/>
We found out too late that a mix of some of our transmit frequencies
lands on one of our inputs.

>> You can't improve things by simply adding more cavities. All you'll

>
>And that's the answer I need.

You might find it easier to build a UHF repeater. With 5MHz spacing,
the cheap mobile duplexers will work with low power (<25w) radios.

one might be able to cascade two of them, but Rob's point about Q is well taken.

It depends on whether the problem is the "depth of rejection" or the "steepness of skirt". A single resonant unit has a narrow spike on top of gentle shoulders. Say one section has Q of 1000 (i.e. the 3dB bandwidth is 100kHz for 100MHz center frequency), but the rejection at 1

MHz away is only 20dB. I could cascade 3 sections, tuned exactly the same, and I'd have 9dB loss at 100kHz, and 60dB rejection at 1 MHz away. The 3dB bandwidth might be around 30kHz, or, you could stagger the tuning slightly to get a little broader flat top, but keep the 60dB (i.e. moving the center frequency of one cavity by 10kHz won't change the attenuation at 101 MHz)

The design challenge is that you need to suppress the transmit signal (at, say, 50W, +47dBm) low enough so that the front end of the receiver can handle it without blocking (say, you want it down around -50dBm). With our not so hot cavities described above, you'd need to stack up 5 sections at 20dB per section to get the 100dB suppression. Well, that's not so great, because you probably now have a bunch of additional loss in the receive path, AND you've got a real tuning chore on your hands to make sure that all of them are tuned appropriately to get the required bandwidth.

Enter the idea of a notch. Let's say our example is 101 MHz Tx and 100 MHz Rx. Rather than rely on the "far away" response of a resonator to suppress the transmit, I can put a 101 MHz notch filter on the input to my receiver. If I can get 30dB/section rejection, then 3 or 4 sections will knock the Tx power down low enough to not block the receiver's front end.

But wait, there's more... that Tx isn't a narrow spike. It has phase noise sidebands that go out fairly far. Unfortunately, the run of the mill transmitter might only suppress "off channel spurious and noise" by, say, -50dBc (and a rig designed to operate half duplex is probably worse). That means that your 50W (+47dBm) transmitter is putting out -3dBm *at the receive frequency*, so no amount of filtering on the receive path will help. Again, enter the notch filter.. you put a 100 MHz notch on the output of the transmitter.

Now.. as Rob points out, the Q might be kind of low. If the Q is, say, 100, then that 100MHz filter is 1MHz wide, and by the time you cascade enough to get the BW down, the loss will be huge.

As you can see, this whole duplexer/diplexer/multicoupler design thing can get pretty complex, and there's not usually a simple cookbook answer.

This will actually help a bit

The free space attenuation for 10 meters at 144MHz is
32.4+20*log10(0.01)+20*log10(144) 32.4-40 +43.2 = about 36dB.

If your Tx is 20W (+33dBm), then the receiver is going to see about
-3dBm at the Tx frequency.   If you want to get the Tx signal down to
around -40dBm or so, you only need 30-40 dB of attenuation at the Tx freq

Then there's the Tx phase noise to worry about. Figure it's 60dB down,
so +33-60-36 = about -63dBm.. probably enough to completely mask any
received signals (what's your sensitivity.. -130dBM?) so you need a
notch with 70dB rejection on the output of your Tx.

You're 600kHz away, implying you need a Q better than a few hundred.
If you just tune up some of those cans for that, and the Q is too low,

then you'll be attenuating your transmitter.

Any reason why you're using a split of 600kHz? Why not go to a non-standard split to make life easier. Pick two frequencies 3 MHz apart (assuming you can get them coordinated, which is more a political than a technical issue)

Don't forget that in Region 1, the 2M band is only 2 MHz wide, the
bottom 500 kHz is dedicated to SSB and the top 200 kHz is for satellite.

True enough..

> Incidentally, I don't consider it my job to supply test data for MFJ.

> results.

Why should they bother. They have someone do a design that seems to work acceptably well, and they sell it at a bargain price. You want published test data and test procedures and it costs more. I'm sure the Tessco catalog has something of comparable performance that comes with test data (heck, you could have the mfr test the very serial number unit they're shipping to you, for a price<grin>)

but sufficient for measuring Z of an antenna, if that's the route you want to go.

>
> Pardon my ignorance, but what's that?

More common in power electronics, but basically you put the UUT in series with a known reactance and known resistance, and measure the voltages across all three. Then you can solve for the resistance and reactance of the unknown. Back in the day, this was solved graphically, but these days, you can do with a spreadsheet or calculator. The trick is that there are often 2 possible solutions, but usually, only one is "reasonable".

Yeah, but I'll bet the transmitter in a WiFi node doesn't have a particularly good match either.. so you could come out better or worse. 3dB loss on top of 15dBi gain is still a net of 12dB over whatever little antenna there was before (if it was even 0dBi)

well.. good match at 200 ohms... I was thinking 50 ohms, so it's equally sucky over the entire band.

80 MHz out of 2400 is, what, about 3% BW? that's like 5MHz on a 2m antenna.

these sort of yagis actually are fairly broadband. Note that all the
directors are the same length, too. What they don't typically get is a
lot of gain for the length.

yeah, but using LMR-400 with that $20 antenna wouldn't necessarily be
the expected application. It's sold as a "laptop range enhancer" for
the most part, and I'd expect 3-6 ft of some small (lossy) flexible
stuff. I'd worry about the LMR-400 bending the antenna.

Oh.. I didn't see that.. so the beamwidth and directivity are
consistent. Nice that back of the envelope estimation theory works.

The elements are lossy, aren't they? That will improve the match (and
reduce the gain). Sort of the same idea as the Terminated folded
dipole.. add loss, improve match. And just like for that kind of
application, I think what they're selling here is "some gain, and some
directivity, at very low price"

>

> be 50 ohms.

I wouldn't.. For that matter, the source impedance probably isn't 50
ohms in the box its connected to. Just looking over some MMIC data
sheets I have here, it looks like they have 2:1 as a worst case and
1.5:1 typical..

This kind of stuff isn't designed like high performance RF systems. They
pick the cheapest amplifier, often don't care much about DC power
efficiency, and cobble up some sort of output filter that keeps the
spurious down low enough to meet Part 15. It's not like specsheets for
consumer WiFi gear actually give you power "at the connector" or
radiated power. All they care is that they don't bust the FCC limits,
and not be "too low" that they'll get consumer complaints.

>> I wouldn't take the fact that it has a 50 ohm

No.. I think its not that they think they have a good match, I think
they just don't care, because in the application, it's "good enough".
They're not designing a deep space communication link where they have to
eke out every last hundredth of a dB to get that 10bps through.

Sure, that does make it harder. The OP is in region 2, though, where there's 4 MHz theoretically available)

<flame protective suit on> And of course, a lot of the band plans are basically gentlemen's agreements and have no force of law. As long as you don't interfere with someone (challenging in some geographical locations), you can pretty much do what you want.<flame suit off>

I wouldn't want to put input or output on 144.2, for instance.

But looking at the ARRL band plan, you could put your input up at 147.6-147.99 and put your output at 145.5-145.8 (Misc and experimental, per ARRL).. not quite 3 MHz, but close, and a whole lot better than 600kHz.

Here in the Los Angeles area, either TASMA or the anti-TASMA folks would probably round up people to have you tarred, feathered and run out of town on a rail, no matter what you do. In any case, things move so slowly that unless you were hideously inconsiderate and egregiously interfering, you could probably run for a year or more before it would get too nasty.

There is a 147.585/144.930 pair labeled for "portable repeater" in the TASMA plan (max 72 hrs/month).. that's 2.5 MHz apart (to make filtering easier). They also say 144.310-144.375 is for simplex unchannelized, but I've not heard much on the air there..for an experiment, it would probably work.

If your intent is to experiment with the cheap  duplexer, what I have to
offer is irrelevant.  However, if you aim to build a repeater, consider
getting your isolation over distance (much greater than 10m).  Put the
transmitter and receiver a few km apart and link them using another band
authorized in your area (440?).

I encountered this in Key West Florida some years ago.  Worked fine there.

I think he is in Region 1. He posts with 2 callsigns, one is a 4X1
(Israel) and mentions:

but my 2m band is only 144-146
mHz, and the repeater portion is really just 145-146.

> <flame protective suit on> And of course, a lot of the band plans are
> basically gentlemen's agreements and have no force of law. As long as

Sure, but to get a permit for unattended operation, at least over here,
you'll need to abide to the band plans.

(in fact in my country, Netherlands, it is even worse: the repeater
frequencies are not coordinated by the ham community itself, but by
the equivalent of the FCC. they work strictly by a set of rules
originally drafted by the amateur societies, in the days the bands
were still overcrowded. arbitrary figures were put in those rules
regarding things like minimal desirable distance between repeaters,
maximum height of antennas, maximum EIRP power, that were originally
just there to regulate the inflow of new repeater projects a bit, so
everyone would have a fair chance of running a repeater. if you were
a few km too close, had an antenna a bit high, or similar, it usually
wasn't a problem. but one day an amateur who got refused a license
went to court claiming that others had gotten a license while not being
within the rules, and as a reaction the authority now strictly follows

the rules and refuses every application that does not fully conform to all the rules. of course, operating on one of the reserved repeater channels is one of the rules.)

It is done here on 10m, where the duplex offset is only 100 kHz and
a duplexer is physically very large.

However, what I hear from the repeater team is that one is in fact
building and maintaining 2 repeaters, doubling the chance of any faults
and problems. Setting up the 10m repeater was much more work than
everyone envisioned, and many had experience on 70cm etc.

Yup. Two repeaters. But avoiding "cans" just might be a blessing.

My local club has a repeater using new electronics but an old duplexer.
I hate periodically re-tweaking the duplexer but
I'm the only one with the spec-an/tracking generator, so I'm it.

The repeater maintenance budget will handle a new duplexer soon.
Hallelujah!

Sal

Thanks, Richard!

But help me understand this:

> All of the lighting protectors you have
links to guarantee you will see a couple of hundred volts across the
terminals.

http://www.universal-radio.com/catalog/protect/5611.html says

* 230V DC discharge voltage =B115%
* Max 1000V surge (1x 40 =B5S duration)
* Max 6000A surge (1x 40 =B5S duration)

Which tells me that if the incoming current exceeds 230V, it dumps up
to 1000V and 6000A to ground. Right?

Rees

Sort of (voltage does not dump, so to speak).

Hi Rees,

The voltage in excess of 230V sustains the dumped current. The 230V is still there, all the same.

That is to say that the resistance of the gap is (for all practical purposes) infinite at voltages below 230V. For voltages applied that exceed 230V, the resistance of the gap is 230V/2300A = 0.1 Ohm.

I chose 2300A both for ease of math, and as being representative.

Hence the gap undergoes a astronomical change in resistance in a very short time (about a microsecond or less).

This is great fortune to the house's protection. This is poor fortune to the radio's first transistor which resides in an environment of, at most, 9V to 12V as a supply for gain, and 0.5V as typically the highest voltage seen at the input. Transistors are rated to sustain higher voltages, typically in the 10s of volts, sometimes higher.

230V to 1000V surge (as guaranteed) offer a speedy death. Of course, of the original source being orders of magnitude greater, lightning boosts speedy death to instantaneous (within nanoseconds).

Let's take a scenario closer to experience, and one that could easily be likened to a near death experience at that. Open the hood of your car, grab an unconnected spark plug lead with the end just a tenth of an inch from the engine block (a common test of the ignition system). You observe a spark. Dare you hold the metal clip where that spark is jumping from it to the block? Dare you even hold the lead on its insulation? The gap guarantees a certain voltage, and the system guarantees a certain current (otherwise you would be forever stalled in the driveway).

Why the hesitation in holding this lead, IF ALL the voltage and current is dumped into the block? Experience will inform you of why you hesitate, and why the transistor fears elevated potential.

An antenna invites access to elevated potentials from many sources other than lightning. Even on a clear day, a dipole can accumulate enough charge to make the spark gap sizzle. This would be extraordinary circumstances in some parts of the US, and typical in other parts. Yet and all as this may be commonplace, radios still play and life goes on. There are many other factors to consider insofar as what the input transistor has to suffer or enjoy.

A local job lot store was selling 100' rolls of #18 speaker wire. I bought as many as I could. I use it for not only hf antennas, but am making open wire line with discarded Bic pens as separators (there was an article in QST about this). I have had a lot of success with this.

Pictures?

At the suggestion of a fellow NG user, I now read NGs via Eternal September*
and I do not see the hot actress posts. Text-only groups, they say, which
is fine with me. Reviews say only 800 NGs -- but they have my two.

I have a Realistic PRO-2003 AM/FM scanning receiver for sale. It is in very
good shape and comes with the manual. I'm asking $45 plus postage for it.
You may contact me off the newsgroup.

Thanks

Henry

I have no experience with 4nec2 to speak of, but what it sounds like is for an optimizer to work, you must first describe (name as a variable) what characteristic you would like to vary until the optimizer achieved an optimal result.

One guess for a three element yagi, I would suspect you would name three variables, the elements, changing each by by an incremental length (another variable) at a fixed frequency (another variable) for maximum gain (another variable) in a particular direction (another variable). Having said that little at seven variables (some fixed in value), it is quite a page full of algebra stated in a formulaic way for the optimizer (However, I fully expect that would be in a table description, not a literal formula).

Having said even that little, it lends a peek into the number of all the combinations and permutations of design this leads to. Each variable taken individually against all the possible others - and then repeated for the others in turn - leads to what mathematicians call Combinatorial Explosion (you don't have enough time to wait for the best solution). This is where constraints are added to the algebra, and you offer "close enough" as one of them to limit testing.

>formula without knowing the arabic numbers first?

Proving the validity of numbers consumed a volume of proofs back when Whitehead and Russell wrote "Principia Mathematica." It was logically dead on arrival BEFORE it was published - and yet it was the best description of simple math known. Calculus was simpler as it is principally symbol dominated.

Hi, I am in the UK & am interested in trying a Par Electonics Omniangle OA-144.
I have come up against the problem in that they are not available here, I know Universal Radio used to stock them , however they are listed as discontinued, they would not export to UK anyway.
I have been in touch with Par Electonics , who manufacture them & have been advised that they will not export to the UK either, they also stated that they only deal with Amateur orders about 7 days a month on a variable basis , so even if I came over, I could not guarantee to hit their ordering period.
So I have 3 questions,

1. Has anyone got a surplus OA-144 they would be willing to export to the UK

2. Would anyone be prepared to source one from Par Electonics & export it to the UK

3. Has anyone got the technical details for one, particularily what is in the matchbox, is it only a 1:1 current balun or is there other jiggery pockery going on in there, so that I could attempt a hombrew version.

Chris

Are you using symbols, or did you hard code all the dimentions in ft
or meters? The optimizer won't work without using symbols.

4NEC2 forums. Where to ask such questions:
<http://fornectoo.freeforums.org>

>Oh, how I hate this.

If it were easy, it would not be fun.
One must suffer before enlightenment.

>Praise Bill Gates for his user-friendly WINDOWS
>and to hell with all amateur softwares.

If you were around in the bad old days of computing, you might be
praising Bill Gates for saving us from the evils of big computer
companies. There was a time when you had to buy pre-formatted
floppies to work in DEC PC's, and when every machine had a different
floppy disk format. Anyway, your frustration with not reading the
manual and learning to use 4NEC2 has nothing to do with Windoze or
Bill Gates.

>Nowhere in the helps and getting started they explain that.

True. Found with Google in a few minutes:

4NEC2 tutorial including optimizer and evolver:
<http://heplx3.phsx.ku.edu/~dzb/antcal/nec-files/_GetStarted.txt>

See section 5.

Video of optimizer (25 min):
<http://www.youtube.com/watch?v=kYy6Yur127A>

>I do not want to learn from examples,

Then you will fail or at least be more frustrated. Hacking your own path throught the wilderness is far more work than following in someone elses footsteps.

>I rather work from the
>basics upwards. Would anyone learn math from a calculus
>formula without knowing the arabic numbers first?

Most certainly possible. There are numerous tools the devices that I use with only a minimal understanding for how they work. For example, there are many drivers on the road that could not even begin to explain how a gasoline engine works. (Hint: Carnot heat engine). I suspect that such basic knowledge would not improve their driving ability.

>Am in a baad mood tooday.

Have a better day.

Rees,

The use of a device such as this that purports to protect the radio from a differential signal impressed across one interface could lure you into a false sense of security.

It does not eliminate the effects of elevation of the 'grounded' sided of the interface above real ground, and especially relative to other equipment. Of course, if the radio has more than one interface (eg a power lead), the problem is much greater than protecting it against a differential transient on that interface.

It is entirely possible that you do such a good job of protecting the input interface, that the receiver is destroyed by a transient from the power cord (if it uses one). You must take the bigger picture into account.

Then there is a question of the damage threshold (current / time profile) for the interface, the expected current waveshape, and the response characteristic of the device.

Whilst a high performance FET might be destroyed long before a gas tube fires, even one doped with radioactive isotope, on the other hand, the input stage of a HF receiver with the input attenuator in circuit might survive without protection.

It is a really complex problem, and the risk is that spending some small money migth delude you into a false sense of security.

I am with Richard, don't take less than competent measures for possibly worse outcomes.

Owen

Rees,

The use of a device such as this that purports to protect the radio from a differential signal impressed across one interface could lure you into a false sense of security.

It does not eliminate the effects of elevation of the 'grounded' sided of the interface above real ground, and especially relative to other equipment. Of course, if the radio has more than one interface (eg a power lead), the problem is much greater than protecting it against a differential transient on that interface.

It is entirely possible that you do such a good job of protecting the input interface, that the receiver is destroyed by a transient from the power cord (if it uses one). You must take the bigger picture into account.

Then there is a question of the damage threshold (current / time profile) for the interface, the expected current waveshape, and the response characteristic of the device.

Whilst a high performance FET might be destroyed long before a gas tube fires, even one doped with radioactive isotope, on the other hand, the input stage of a HF receiver with the input attenuator in circuit might survive without protection.

It is a really complex problem, and the risk is that spending some small money migth delude you into a false sense of security.

I am with Richard, don't take less than competent measures for possibly worse outcomes.

Owen

I am making progress, though.
Got the optimizer running and edited a few of the example files
to have the variables selection available.

Works.

Now I watch the optimizer quickly de-optimizing the antennas
until they radiate into the wrong direction or get stuck in a
circular radiation diagram. In one case the optimizer bent
and rotated the dipoles around, I bet no specialist can do what I can.

Real fun, that is :-)

>
>Video of optimizer (25 min):

>

Yeah, thats good. Sitting back and watch.
Thanks for the idea of watching the Youtube demos.
Better than endless trial-and-error.

My goal is to find out what makes a direction finding antenna
different from a gain optimized antenna.
F/B ratio is all that matters for ARDF, for example.
Gain is secondary and side-lobes should be absent.
I must get that NEC working by all means.

Regards,
w.

That's easy (having helped design 2 commercial direction finders). Low
side lobes and good front to back. Gain is well down the list of

requirements. Side lobes will drive any direction finding scheme towards insane results by generating false peaks in the direction. The ability to recognize these is a function of how much time you want to put into the software. Reflections will also cause problems, but more so with side lobes.

To prove a point, I once threw together a rotating antenna direction finder using a low gain directional antenna (but with low side lobes, and no rear lobe). Due to the low gain, the -3dB beam width was a rather wide 60 degrees. I rotated the antenna slowly, and the computah made lots of signal level measurements. The result was that I could determine the direction within about +/-2degrees. Of course a higher gain antenna would resolve the signal direction much better, and could probably be rotated faster, but all would be much larger. However, there's a problem. High gain antennas tend to have boresight errors. Small asymmetries, such as mountings, gamma matches, and baluns, will have an effect.

>F/B ratio is all that matters for ARDF, for example.

F/B could be considered a side lobe at 180 degrees. Like other side lobes, it needs to be minimized.

>Gain is secondary and side-lobes should be absent.

Absent is difficult. Minimized might be a better goal. With a log amp driving the signal level measuring device, three orders of magnitude should be sufficient.

>I must get that NEC working by all means.

Slow down. Such things take time.

What manner of direction finder are you building and what frequency? Doppler? Rotating antenna? Phasing? Time difference of arrival? Homer? Adcock? Ouija board?

Sorry, bad mood again.
Watched the tutorials on Youtube.
Remarkably he starts loading an antenna and then deleting the elements
to get a blank builder screen.
The 4nec2 cannot start with a "new" file, it must load something from
before. Only then I may select NEW. This is a bug.

I copied the moves from the tutorial on my NEW antenna,
and I cannot place a source on the dipole. Does not work.
No error message, nothing.
So I will load some old antenna, delete everything and try again
as shown in the tutorial.

Within 5 minutes of work I have a list of 5 errors,
program errors, repectively bugs, mis-leading the user.
Can't type as fast as the bugs occur, I just described only one.
Of course I have no right to complain because it's free.
Yeah.

Now I watched the tutorial again and again
http://www.youtube.com/watch?v=3AqMq0J3WBc
and after 14:11 he adds a voltage source.
```

He does a horizontal movement with the cursor on the dipole wire
and only then the 4nec2 will place the voltage source on the dipole.
He does not mention that or explain that move.

This stupid bug -and a program bug that is, and a large one-
this stupid bug has cost me 2 hours of struggling.

Ready for the next bug.

I'll see if I can get pix on a web site I'm working on. You use cable ties doubled up inside the barrels to hold the wires. The Write Bros. pen barrels are about 5" not including the swage, and if you cut it in half, 2.5" should be ok for up to 10M.

Well, there is no "new" button or choice under "File". Ask Arie Voors
for the feature. It seems easy enough to add to the program.

>I copied the moves from the tutorial on my NEW antenna,
>and I cannot place a source on the dipole. Does not work.
>No error message, nothing.
>So I will load some old antenna, delete everything and try again
>as shown in the tutorial.

Well, I've never had that problem because I don't try to "paint" the
antenna using the isometric or 3D views. It's not accurate enough
unless you snap to a grid. I create the antenna either externally,
with a text editor, or using the spreadsheet style editor. I import
that into 4NEC2 and make any necessary changes (and fix any screwups).
For geometric shapes, I use the external shape generator, which will
do surfaces, parabolic dishes, etc. 4NEC2 is not a drawing program.

>Within 5 minutes of work I have a list of 5 errors,
>program errors, repectively bugs, mis-leading the user.

Impressive. You might want to search the 4NEC2 forums to see if any
of them have been previously reported.

<http://fornectoo.freeforums.org>
Note that there is a section specifically for requesting new features.

>Can't type as fast as the bugs occur, I just described only one.
>Of course I have no right to complain because it's free.

In my limited experience, people complain more about free software
than paid software. That's usually because the author(s) encourage
feedback in order to improve their product.

>Yeah.

Thanks for ignoring my questions.

```

Nobody does backups until after they have lost data. I've been using 4NEC2 for at least 7 years and have never lost a file. Well, I have accidentally overwritten a file, but that was my fault. When I tinker with antennas, I save multiple versions of the same design with the version number appended as in file001.nec. This way, if I make a horrible mistake, I can go back to a previous version and try again.

>Now I understand why it's free.
>Can't charge money for bugs.

Well, that why we have alternatives to 4NEC2 and why I don't charge for my free advice:

###########"Backup, you say it". ###########

When optimizing for F/B also 4nec2 results in a too short driven
element, same as YAGICAD, they obviously use the same formula,
(a long two-liner) from literature.
I actually built antennas following that prescription,
and they do not work without additional corrections,
e.g. a very long hair-pin match.

Imagine a 3 element 2 meter yagi,

```
|
|               |
|       |       |
|       |       |
|       |       |
|       |       |
|       |       |
|               |
|
```

Something is wrong here with the capacitive driven element.
Now I am having a hard time, because I want to find out in
what differs a gain optimized vs a F/B optimized antenna
and it is questionable whether that can be done with software.
Have not tried other programs yet.

http://imageshack.us/photo/my-images/837/snc14096a.jpg/

The Front to Back ratio is very frequency dependent
http://imageshack.us/photo/my-images/220/fbratio.jpg/
(Without the hair pin match)
http://img5.imageshack.us/img5/3479/snc14112hairpin.jpg

Therefore I put the driver on a slider
http://img841.imageshack.us/img841/8530/snc14097small.jpg
which allows to adjust the working frequency of the antenna
over a >10 MHz range on 2 meters. Adjust for minimum reception
from the back and the antenna is optimized for that frequency.

Now I want to collect a list of recipes which allow to build the
antenna without having to tweak it on the antenna analyzer.

A similar design once was offered by DIAMOND MAY1000
http://www.rfparts.com/diamond/MAY1000.html
Look at the frequency chart
http://www.rfparts.com/diamond/pdfdocs/MAY1000%20Adj%20Chart.pdf
With that antenna one could adjust the element lengths *and*
the distance between the elements, which is crucial for the F/B ratio.

A Yagi with fixed element positions can only be used for 1 frequency
(within a very small range) and therefore may be impractical
in many situations. The CEBIK tape measure antenna with their
water-pipe construction could be easily modified with a moveable
center element.

Helmut,

your ranting and raving about 4Nec2 seem entirely unfair, the 'bugs' that you complain do not seem to be bugs at all, just the way the program works; which is not to your liking.

Placing sources requires that you click whilst away from the wire and then drag the source onto the wire. This is not a bug, just the way that the author chose to do it.

In many years of using 4Nec2 I have never had it loose a file, so I can only assume that there is some sort of problem at your end.

Yes, it would be nice to have a 'New' button, but again not a bug, just the way that the program works. If this minor inconvenience pains you that much ask the author to add one.

Regarding optimization the phrase 'garbage in garbage out' springs to mind. Optimizers are just that, optimizers, they WILL NOT take a rubbish design and turn it into the perfect antenna.

Optimizers rely on finding minima (or maxima) in the set of parameters that you supply, so unless you are close to a good design it is very likely that they will 'get stuck' in a local minima and then home in on

something other than an optimum design. So you have to have a good
design to start with and also not try to optimize to a set of
unrealistic goals. This applies TO ALL optimizers not just 4Nec2.

Regards
Jeff

So, the software is not perfect... but some of your complaints are are
result of your own ignorance of modelling, NEC and 4NEC2.

Helmut, your vitrolic rant doesn't strike a chord with me.

Right now, Arie has some personal issues that we would all rather not have
in our lives, and yet he is finding time for some problem resolution.

Arie, I dips me lid (that means "hats off" in Oz).

Owen

Show me the place in the manual or help where that is described.
Normally we do drag and drop, but here we must drag, drop & move.
Made me crazy, but no longer now since I know it,
and I will keep it a secret and not tell anyone.

Of course, it's free, so it must be my fault.
From the little programming I did, I know it's 99% user interface
and 1% programming the more interesting part.

Firstly it is not 'drag, drop& move'; it is click, drag & drop! Try
reading the Help a little more closely, you will find that it says:

"The next thing to do is add a voltage-source. While still in Add-mode,
click the 'Source button' (right of the 'Wire button'). Next click and
hold down your left mouse-button somewhere in the picture-box. At the
current mouse-pointer position a new source-object is displayed. Drag
the source-object to the middle of the second wire, just between the two
lower wires-ends of the feedline and release the mouse-button. When
properly positioned a new source is now added."

No one else reports this problem so draw your own conclusions!!! The
fact that it is free has no bearing on it.

>
>> Yes, it would be nice to have a 'New' button, but again not a bug, just

Have you contacted the author and asked for this feature? No? I thought not. Again the fact that it is free has no bearing.

Yes that is the way it is with ALL optimizers, not just 4nec2; gigo.

No one is forcing you to use 4nec2, however, no one else seems to be
having the problems that you claim are 'bugs', perhaps you should have
more patience, read the help more closely, and not be so quick to criticize.

It does not work as described, when inserting a source on a dipole
wire in the center segment, one of the first things to do in Example1.

Utter Rubbish!!! It works EXACTLY as described!!!

Hold down the left mouse button, drag the source to the segment where
you wish it to be, release the button - exactly as described!!!

Jeff

Then when you set up your optimization criteria in 4nec2, weight the F/B or F/R with 100% and the others with zero (although sometimes, you may want to weight forward gain at 10%, just to keep it from driving to zero gain)

Does your model have symbols defined (using the 4nec2 specific SY card?)
That's what it uses to populate the list.

Which editor are you using? If you already have a NEC input deck, it's
easiest to use the non-graphical editor.

What are you optimizing for.

Sure, you can whine about wanting better help files, but face it, Arie
is providing the product for free. If you are already proficient in
NEC, the help provided is fairly useful. If you are learning if from
scratch, yep, it's a pain.

Unlikely...
4nec2 is just driving the finite element NEC engine underneath. YagiCad
uses analytical approximations.

NEC is *very* sensitive to segmentation, spacing, and wire diameters,
etc. particularly when close together or angled. The NEC4 engine is
quite a bit better, but you're probably using the default free NEC2 engine.

To effectively use this kind of thing, you need to be pretty aware of
the limitations and peculiarities of the underlying FEM codes. While I
wouldn't expect someone to have read the theory manual for NEC2, you
might want to check out some of L.B.Cebik's writeups on using MoM codes,
or the stuff in the ARRL Antenna Compendium from time to time.

> Something is wrong here with the capacitive driven element.

Depends on what you were optimizing for.
If all you said was "drive F/B to maximum", then it won't try to get you a decent match, all it will do is drive to having element currents that optimize for F/B, which will almost certainly have an evil feedpoint impedance.

> Now I am having a hard time, because I want to find out in
> what differs a gain optimized vs a F/B optimized antenna
> and it is questionable whether that can be done with software.
> Have not tried other programs yet.

What I do is not try to use the optimizer to design the whole antenna including matching network. I optimize the basic element design first (without matching network). Then I add the matching network, hold the element spacing and length constant, and let that optimize. Then I go back and allow element length to change, but hold matching network dimensions/component values (I tend to use lumped element matching networks) fixed.

It's an iterative thing because it's tough to specify an appropriate optimization cost function with a simple interface. What you really want is something like "optimize F/B, but keep the feedpoint impedance >20 ohms and <100 reactive ohms"

>
> A Yagi with fixed element positions can only be used for 1 frequency

> water-pipe construction could be easily modified with a moveable
> center element.

this is just not true (otherwise the SteppIR wouldn't work.. it has fixed element spacing and works over a huge (>1 octave) frequency range) with fairly good performance.

One can also do similar with fixed spacing, and fixed length, and reactive loading of the elements at the centers.

On 8/12/2011 2:23 AM, DrYattz wrote:

> Having but recently returned to the world of shortwave radio, I'm trying to be better informed about technical and safety issues than I was as a kid. Now a homeowner with a mortgage and a homeowner's insurance policy, I'm worried about lightning protection. I'm receiving only, not transmitting. I have a ground rod just outside the window where the antenna wire enters, and I intend to disconnect the antenna outside the house when I'm not using the shortwave. But I want to be extra careful!

Separate two issues:
1) having the house not burn down
2) protecting the front end of your radio

#1 is fairly straightforward and what your homeowner's insurance company might care about

#2 is pretty darn tricky, but the homeowner's insurance company doesn't care much about your radio.

As others will point out, a single rod pounded in does not generally a code compliant ground make. And a single rod pounded in might actually make things worse, as far as damage and destruction goes.

The goal is to get the lightning energy to go "somewhere else" than in your house. A secondary goal, since sending ALL lightning energy somewhere else is very difficult, is to not have the remainder destroy the radio.

First off.. almost all amateur antenna installations do not fully comply with the electrical code (and before I get flamed.. let me ask all you would be commenters: do you have a listed antenna discharge unit? are all your conductors no less than AWG 14 hard drawn copper or copper clad steel? Is your antenna lead in entirely contained within a metallic raceway? I thought not.. pace...we're going for practical here)

That said, I think that a "good faith" effort to do the right thing will help, and besides, unless you're in a disaster area, insurance companies generally don't work to try and deny claims on flimsy basis. there's the whole "reasonable person" aspect and your looking for decent information is a good start of what a "reasonable person" would do.

You might take a look at the safety chapter in the ARRL handbook as a start (the library has it, almost certainly, or you can find someone who will loan it to you).

A antenna discharge unit (open spark gap with a spacing of a few tenths of an inch) to a ground rod or rods will go a long way towards keeping most of the lightning current out of the house. It takes several kV to jump the gap, but once the gap is conducting, the voltage drops to a few tens of volts, and that's nothing in the overall scheme of things where there are many kilovolts along your wire.

The real problem comes in with the fact that no matter how good a job you do in connecting that gap to the rod, there's going to some distance, and some voltage drop between the voltage at that arrestor (during the strike) and "the rest of the house ground potential". If your radio is sitting in the middle, it WILL conduct, and it WILL be exciting.

The idea, then, is to make sure that no big voltages occur across two terminals of the radio (that could either be antenna and ground terminal, e.g. coax, or antenna and power supply).

The big deal is the AC power.. your wall socket is close to ground potential (in terms of kilovolts, anyway). So if your radio's antenna is at 2 or 3 kV, and the power cord is at ground, your radio will fry.

Run the radio off batteries? As long as you're not touching it, and it's not hooked up with an audio cable to your PC or something, then it just floats up to a few kV, and then, floats back down.

Most UL listed wall wart power supplies these days can hold off several thousand volts between inside and outside (that's the so called "hi pot" test rating).

Beyond that, it starts getting into gas tubes, and similar stuff to try and protect the innards of the radio. How much does your radio cost? Do you want to spend hundreds of dollars on surge suppressors to protect a $200 radio?

it's also remarkably hard to build a very sensitive receiver that will tolerate even a few tens of volts on the input.

That may be so at DC or 60 Hz, but it may be relatively transparent to the spectral components of lightning discharge current, components that may me significant to 100MHz or more.

There is no simple broadband equivalent circuit of the power transformer, but at 100MHz, it might look more like some series capacitance of the order of 100pF from primary to secondary for common mode excitation... and that may well allow damaging currents to flow (without insulation breakdown or permanent damage to the transformer), whether driven from the coax shield, the power line, or more likely, both.

Just another factor that makes design of bullet proof solutions so challenging.

Owen

God The Father says,
" If you go some place tonight and you say, 'Do
you know Who spoke at a meeting I was at?' and you
told someone in a loving way, they might even laugh.
But that's what they did to Moses. He said, 'I have a
Message, you must listen.' 'Who gave the Message?'
'The Almighty One.' 'Who are you, Moses, to have
Him speak? Who are you, for Him to use in such a
grand manner?' And I say to you tonight, Moses'
answer is and was the same as hers."

REVELATION DELIVERED THROUGH FRANCES M. KLUG
ON OCTOBER 23,1991

GOD THE FATHER

" In the time of Moses, when Moses stood amongst people such as are present here tonight, he too did not want to look or feel different in any form, in any way, but when I took him to the mountain and I held him there, he was in complete obedience to My Will and My Way, My Words, My Direction, and What I wanted delivered for a long time to come.

I gave him very little rest. I instilled in him a great degree of knowledge, a great degree of wisdom and a great degree of understanding, and an ability to pass this on verbally, physically, mentally, emotionally and spiritually, for the good of Souls. All the Words that I gave to this man on a mountain were not delivered fully by those who were taught What I wanted to be taught.

Today, in the time in which you live, you have much responsibility. Many men of all races, all colors, all creeds, would say I would not use a woman, I would use a man at this time in the world. How can man decide what I would use, My Reasons for who I would choose, and yet men stand in judgment, even on this night, against this instrument who speaks My Words distinctly, lovingly and purely, through the Soul, to you.

I use a Soul. The Soul, as Part of the physical, is the manner which and how I speak to you. Many men say, 'The Father would not speak.' Who knows better than The Father, who would speak?

To speak through an instrument, men of all kinds would expect Me to shout. If I am angry I shout, but there is no reason to shout on this night to you, for the Soul I hold, the Soul I speak through, is as your Soul Who listens intently to My Words on this night.

I want you to read again and again the Words I spoke through this Specific Letter to all men.*

So many in the world imitate My Form of Ecstasy in a human being. Their manner of so-called acceptance to someone speaking through them has many versions and many false backgrounds.

Why would I not speak? You know I have spoken before. I use one seed to deliver My Will, My Way.

The Soul accepts the Delivery. The physical says, 'God, not again,' but then submission of the will to My Will, What I Want Delivered, is important to Me.

Many men and women walk the earth, wanting a Special Blessing such as This, but I, your Father say, 'The degree of responsibility is beyond man's ability to discern; a Power a human body must accept at a time such as this, it is indiscernible by human standards.'

Thousands and thousands and thousands of Words have been given to you and others, telling of the responsibility of the Soul, That Portion of Me that is within each one here and in each human being throughout the world.

I will tell you something you could not recognize now, as My Words flow through this instrument who looks like you, feels many ways like you feel, but there would be a joy in the Words if the joy would extend to you happiness, laughter, and something to relax you so you could leave here and say, 'Wasn't that a fun time?' But I want you to leave here on this night and remember that it was a Blessed Time, a Blest Time, and a Time that is not always repeated in a lifetime.

It is not natural for a human being to want to be held so tightly, because the will wants the freedom to act, but it took a long preparation for this woman you know, to accept this manner of living, this form of speech, this acceptance of My Will, so you could be reached.

I give her moments of lightness, for the physical is extremely frail. The physical I speak through is fragile, and has become more so because of the Power that I use to reach you, for the benefit of your Soul, and to give you the strength to pass on to others, through example, through words, through everything you do.

I have spoken much today, to give her the strength to be with you tonight. It has been a very tiring, difficult time, and what you do not know is she has just apologized because she was so tired, but she speaks like this to Me, but in truth, she would hide her tiredness from you; she always has, and you have My Word, she always will.

If you go some place tonight and you say, 'Do you know Who spoke at a meeting I was at?' and you told someone in a loving way, they might even laugh. But that's what they did to Moses. He said, 'I have a Message, you must listen.' 'Who gave the Message?'

'The Almighty One.' 'Who are you, Moses, to have Him speak? Who are you, for Him to use in such a grand manner?' And I say to you tonight, Moses' answer is and was the same as hers.

You are loved much. There is no preparation for My Words through her. My Words come with Love, Understanding, for you are children that I put in the world.

Every child born to the world is born for a purpose. Every child does not reach the fulfillment humanly expected, but I always look for that Soul to rise above all questions, all wrong, for you see, the enemy is always around, trying desperately to gather Souls, to take That Part of Me that I gave to you at the moment of conception.

You are blessed in many ways. Your presence here tonight is a blessing you could not understand. Your presence here tonight is your will as man.

I hold her deeper than you know. The body belongs to Me, because of the responsibility her will has accepted. I must give her time to relax after this ordeal for, in reality, the human body says, 'I feel I will break, my God, under this task.' So be it."

*Refers to the Revelation delivered by God the Father on October 18, 1991 at 1:25 p.m., which had been read earlier in the meeting, to the women in The Society Of The Little Way.

Designed to receive 54 Mhz to 210 Mhz ...
http://en.wikipedia.org/wiki/North_American_broadcast_television_frequencies
... Not going to work very well unmodified.

Keep the rotor and get an actual 2 meter yagi. I don't mean to discourage you from building antennas. But you would probably be gutting that thing for pieces of aluminum to cut to proper lengths to make a 2 meter antenna.

I was offered (for free) a VHF TV yagi anntena w/ rotor. Question: would this work a 2M antenna? With a tuner, maybe?

Cute cat. However the antenna seems a bit odd. The high carbon steel tape measure elements are not the best for RF conductivity. Good enough for receive, but I would check for RF heating in transmit.

The tape measure is also not a circular rod element. You probably modeled it using a circular cross section. That's probably a good first try, but if you want accuracy, the actual element cross section will be needed. That's what I had to do with this stamped sheet metal antenna:

<http://802.11junk.com/jeffl/antennas/mfj1800/>

>(Without the hair pin match)
>http://img5.imageshack.us/img5/3479/snc14112hairpin.jpg
>Therefore I put the driver on a slider
>http://img841.imageshack.us/img841/8530/snc14097small.jpg

I presume the hairpin match goes between the wing nuts. Looking at the photo of the hairpin, it seems small for matching a simple 2m yagi. It's also a good idea to add a balun and to ground the center of the hairpin match to the center boom.

No sir, your radio already knows that trick. It will feel that it is being cheated by you using speaker wire and will refuse to send RF out the antenna jack. (I'm just kidding.) :-)

But seriously it should work just fine. Treat it as insulated 18 gauge wire. I did use Radio Shack Flat copper Mega Speaker Cable as Ground Radials - I zipped them in half and each package made 2 radial wires.

Activate the source & add button, then click on the middle segment
and expect the source symbol to appear there.
It appears but vanishes in an instant leaving a highlighted segment.
If the sideways motion is not performed, you do not get it.
You have to pull it and that is counterintuitive.
The above description may be correct in that you have to pull
the object. After having worked with dozens of CAD programs
I did not expect such a trap.
Many users claim similar difficulties, the internet is full of them.
Honestly, who reads all the help files, hundreds of pages?

I know there are people who think every bug is a feature.
Those people do not live from their own work,
 somebody else must pay for their living.

It took me 3 days to learn 4nec2 because of a long list of "features"
including data loss and program crashes. "Notify the author"
it suddenly says. The user sits there "What did I do wrong?"
which is a nagging question actually when the fault lies elsewhere.

All that counts is WALL CLOCK TIME.
But it's free.

Well if you don't actually follow the instructions on the Help then what
can you expect! Don't blame the program and then say the Help is wrong
or not there! RTFM.

"click and hold down your left mouse-button somewhere in the
picture-box" then "Drag the source-object to the middle of the second wire".

Jeff

In theory (from the simulations) the Yagi is rather narrowband. Especially the F/B ratio is very frequency dependend.

The SteppIr does vary the elements, if I understand it correctly? For practical reasons they do not change element positions on the boom but sufficiently adapt to each frequency band.

For the same practical reasons I do it the other way round, move the driver element in the 3 element yagi, and leave everything else as is. This is intended for mobile direction finding. Based on the Cebik pages and improved by making it tuneable by moving the driver along the boom.

There is a story behind.
ARDF is a sporting endeavour, where people run around in a restricted area searching for a defined signal, or several foxes, as they are called. The antennas are optimized for the fox frequencies. That's child play compared to real world.

One night I got a phone call from a desperate guy in Bosnia. They had held a model flight competition there, class F1C, and his model airplane flew ten kilometers away.
They put crash transmitters on the models and they range in frequency from 140 to 160 Mhz without any approved frequency raster, just what they can get and not to disturb the neighbour model transmitter. So they need equipment for a 20 MHz range. Most of them use amateur radio handhelds.
The transmitters weigh about 5 grams.

The Yugoslavian Balkan war was just over, where the killed 200000 people by shooting and cutting throats, and the mine fields were still active and most of them still are today. They put fences around and automatic siren warnings. That desperate guy's model airplane was in or near such an area and night doomed. He has searched for the whole day , was exhausted and could not locate it.
"Signals from everywhere and from all directions", he said.
That model was his only one for the competition and very expensive, they cost a few thousand dollars.

"Signals from everywhere and from all directions."
That is a very interesting statement. Did you ever experience such

a situation? I had to place foxes and go after them to find out what
the problem was which the guy described. I expected an easy job,
because I am such an old fart in radio engineering. It was late summer
and corn standing two meters high, railway routes nearby,
high voltage lines criscrossing the landscape, buildings, hills,
mountains, fences, and now imagine it's getting dark and you are
in a foreign country where you never had been before,
between lakes, rivers, wet ditches and waste water canals.
I never knew that 2 or 3 meter high corn fields act as an antenna
array. The power lines and railways are wave ducts of extraordinary
quality, every metal fence collects and reflects and adds to the
reflections from the rocky mountains. Electromagnetic interference
overlays the fox signal until you only hear noise and crackles.
There you go. I hope the reader can imagine what is the difference
to a well planned amateur sport radio fox hunting event.

Quickly I recognized that a fixed-frequency ARDF antenna is
not suited for the task and one must be able to tune the F/B ratio
for the different frequencies the transmitters use, in combination
with a conventional attenuator. If your antenna receives from the
back, you will hear "signals from all directions".

Of course you are right,
but there are thousands of (unread) help pages left.
Should I read them all?

On YOUTUBE another (not me) user said, he falls asleep
after 4 pages of help text (the getting started stuff).
I printed the "getting started" but fell asleep after page 3.

Thank you for the links, appreciate your help.

I fear that in the end I will have to cut and tweak using the
antenna analyzer, and with the time perhaps find
"tape measure correction factors".
Want to keep the design as simple as possible,
and hope it works without a balun or additional tricks.
Am not yet sure if it will work that way, or not.

w.

Well since the instructions on how to add a source are on page one, it
would appear that you went to sleep earlier than you thought!!

Just because a program does not work the way that YOU expect, or perhaps
would like, does not warrant the out and out rant that you started this
thread with.

All of the information on how to run the program was actually there if
you had bothered to read it rather than wasting time complaining about
nothing.

Jeff

>Thank you for the links, appreciate your help.

Y'er welcome. However, I still don't have a clue what you're trying to accomplish. If you want super front to back ratio for a direction finding antenna, you need a wall, not a phased single wire reflector as in a yagi. Something like a dish or a panel reflector will work, but is probably not practical. As you discovered, the position of the reflector is very critical for maintaining the best F/B ratio. It's also very sensitive to frequency. You might be able to make it work with a flimsy tape measure, but it probably won't be very stable in the field.

Permit me to offer another idea. Instead of direction finding by the peak signal, do it with a null. Two identical dipoles, a T connector, and some coax, are all that are required. Space them about 1/4 wavelength apart. Insert a 3/4 wave coax phasing section between the two dipoles. Signals from the front antenna will cancel when they reach the 2nd antenna yielding a cardioid pattern. It will be just as critical and sensitive to frequency and position as your yagi, but methinks will work better. I've obtained 50dB deep nulls with this method. The good news is that you really only need one adjustment on the antenna, which is the relative distance between dipoles, which is easily accomplished by sliding the antenna on the boom. The adjustment range is limited, so an assortment of coax phasing lengths will also be needed. Adjusting the antenna for best null at a specific frequency, prior to transmitter hunting, is a necessary complication.

I also use this method on my home base station to null out a rather strong repeater, so I can talk to a distant repeater on the same frequency. I've also built one using 4 identical rubber ducky antennas for 2meters. It sorta worked but I could only get a 10dB deep null.

Both EZNEC and 4NEC have HF examples of this type of antenna.
cardioid.ez and \models\HFvertical\cardioid.nec

>I fear that in the end I will have to cut and tweak using the
>antenna analyzer, and with the time perhaps find
>"tape measure correction factors".

More bad news. You really do have to TEST your creations to see if the simulations and models are correct. I tend to make far too many simplifying assumptions in my models, which show up as errors in the actual construction.

>Want to keep the design as simple as possible,

Simple is good. Crude is not. Recognizing the difference is difficult.

>and hope it works without a balun or additional tricks.
>Am not yet sure if it will work that way, or not.

It won't work well without a balun. The coax will radiate, giving unpredictable directional indications. You can minimize the effects with ferrite beads, a sleeve balun, or with just a coax loop.

Perhaps reading the Steppir patent might be illuminating:
<http://www.google.com/patents?id=rw6xAAAAEBAJ>
Note that the elements do not change position, only their length.

Exactly.. you can get very sharp nulls pretty easily. For simple
antennas, there's usually an ambiguity, but you can resolve that by
other means.

yes.. although for the most part, if you're looking at the transient from a "spark gap arrested lightning impulse" you probably don't have quite that spectrum.

> There is no simple broadband equivalent circuit of the power transformer, but at 100MHz, it might look more like some series capacitance of the order of 100pF from primary to secondary for common mode excitation... and that may well allow damaging currents to flow (without insulation breakdown or permanent damage to the transformer), whether driven from the coax shield, the power line, or more likely, both.

Could be.

Standler's book on transient protection comments that several studies have shown that most modern consumer electronics can tolerate standard transient impulses (both the 1 us and 6 us rise time variety) of several kV. The not so halcyon ESD days of TTL gates connected directly to the device connector pins are long gone.

Should you read them?

Depends on if you want to make use of the program or not. for ANY
modeling program (and any drafting program, as well) there's a fairly
big first step in the learning curve.

And, because 4nec2 isn't a "drafting" or "drawing" program, it's UI doesn't follow the more common conventions. It's designed to make entering antennas easy for some subset of people. 4nec2 started with just using notepad to edit the NEC input deck and a formatted editor to edit cards.

Folks who start with EZNEC often find using raw NEC decks difficult, because they're used to the tabular model entry of EZNEC.

Folks who start with Visio, pre version 5, find modern versions of Visio a pain, because the UI changed to conform to PowerPoint.

Autocad is certainly not "intuitive" unless you've been using it a while.

For what it's worth, the 4nec2 help files are a whole lot better than the documentation for NEC itself.

Beyond the details of entering the geometry and simulation conditions (which are idiosyncratic for ALL antenna modeling programs.. no two are alike, nor are the input file formats directly compatible, for the most part)

There's a fair amount of "art" in effectively using the programs and understanding the limitations inherent in the modeling technique being used (method of moments on wires for NEC). It's not just a matter of creating a bazillion segments and letting your processor grind away, because there's all sorts of subtle numerical precision issues.

4nec2 (and EZNEC) both provide some amount of help in keeping you away from egregious model errors (segment lengths that are unreasonable relative to wavelength and/or wire diameter).

There's also well known techniques for modeling flat surfaces with meshes that provide results that match actual measurement, even if the model doesn't "look" quite right if you render it.

NEC is very much a power tool like a chainsaw.. you can do things that you couldn't do with hand tools, but you can also do things that you don't really want. It takes some practice and background knowledge to use it effectively.

The value of purpose built modeling tools like AO is that they have a very constrained model space tuned to a particular application, so the program can
a) have a simple model entry (e.g. you can only do Yagi-Uda)
b) have a sophisticated objective function for optimization

NEC is a lot harder: you can enter any geometry from a simple wire to an entire battleship with 100s of antennas.

Hello Rees,

Mostly it isn't the problem to get sufficient signal, but to get sufficient signal to noise ratio. If you can operate it outside the house (with a seperate 12V battery), try this and see whether the reception improves. Move around to find sweet spots. You may have interference from indoor electronic equipment and this will be less when you are outside. Don't run an extension cord to feed the receiver as this may carry interference from inside towards the receiver.

As this receiver is rather sensitive, a large antenna may result in worse reception due to overloading the input circuitry. Here a so called preselector can help, expecially when you have some strong nearby transmitters. If you like constructing, building such equipment can be a nice project.

If outside reception is better, you may need coaxial cable to "transport" the antenna signal to receiver without picking up interference from indoor equipment.

Don't hesitate to come back with other questions or suggestions.

Hi Helmut,

The signal is too STRONG. I'm surprised you have not recognized this common fox hunting problem.

There needs to be an attenuator between the antenna and the receiver.

With the cardioid pattern, there's no ambiguity. With a deep null, and a non-reflective environment, it's easy to use. However, reflections off buildings and hills are a problem. The antenna is roughly an omnidirectional antenna, and reflections will appear to fill in the deep null. Not much can be done about that except to move and try a different location. My favored method is by using a map. Find a position, determine a bearing, and draw a line of position on the map. Then, find a different location, and do it again. Repeat as often as practical generating as many LOP's as possible. Some of the LOP's will be totally insane, but a majority should cross at one point on the map. (This has been automated in software, but a map is good enough).

In 1976, I helped design the AN/SRD-21 homer DF, which DOES have a 180 degree ambiguity.

<http://802.11junk.com/jeffl/AN-SRD-21/>
If the homing receiver works in the same manner as described in the above manual (PIN antenna switch, synchronous demodulator, charge pump, and zero center meter), resolving the ambiguity is easy. Just rotate the homing antenna to the right. If the zero center meter indicates that you should turn back to the left, then you have the correct direction. If it indicates that you should continue to turn to the right, then you have the wrong direction.

This has nothing to do with the topic at hand, but I thought it might be of interest. Some of my ancient comments on Doppler direction finding:

I have seen recommendations that one do this by proceeding in a
straight line, taking bearings at positions of around 1/4 wavelength
or so. The effects of multipath will tend to cause the measured
bearing to wobble back and forth across an arc (as you go down the
line) and the true bearing will tend to be close to the center of that
arc.

I haven't tried this approach myself... but it might combine well with
your "take readings from lots of different locations" approach, by
helping cancel out some of the effects of multipath.

There's a photograph of this technique on a field with little flags at
different distances all oscillating around a single line illustrating it
in some ARRL publication (probably an antenna compendium, but maybe the
handbook or antenna book).

On the schematic diagram that I retreived, the attenuator is only in the
path of the LO-Z antenna, the SO-239 jack -- the one with the threads on it.

The telescoping whip and the High-Z jack are electically almost the same
place, separated only by a single capacitor which couples signals from the
HI-Z jack into the path from the telescoping whip. No attenuator in that
path.

The effects of multipath will tend to cause the measured bearing to wobble back and forth across an arc (as you go down the line) and the true bearing will tend to be close to the center of that arc.
>>
>> I haven't tried this approach myself... but it might combine well with your "take readings from lots of different locations" approach, by helping cancel out some of the effects of multipath.

>There's a photograph of this technique on a field with little flags at different distances all oscillating around a single line illustrating it in some ARRL publication (probably an antenna compendium, but maybe the handbook or antenna book).

I think the photo was on interferometry for direction finding, where they were trying to plot the wavefront pattern. I recall the photo, but I couldn't find it in the ARRL Antenna Handbook (19th edition). However, the handbook does have a full chapter on direction finding (Ch 14) which includes the cardioid antenna.

The purpose of me using multiple bearings is simply to eliminate the effects of reflections. It's not totally foolproof, but better than chasing a single bearing.

There are better ways, but they're usually not very portable. A rotating antenna direction finder can easily distinguish between the incident signal from a reflection. Such direction finders display something like the antenna pattern on a polar display. The incident signal is very steady and does not move in azimuth. Reflections jitter dramatically in both amplitude and azimuth. They also tend to appear and disappear rapidly and erratically.

Rotating antenna DF antennas:
<http://www.rockwellcollins.com/sitecore/content/Data/Products/
EW_and_Intelligence/SIGINT/ANT-1040A_Airborne_Spinning_DF_Antenna.aspx>
<http://www.rockwellcollins.com/sitecore/content/Data/Products/
EW_and_Intelligence/SIGINT/ANT-1040_Spinning_DF_Antenna.aspx>
20 in diameter, 25 in high, 50 lbs.

Another method that I've used is to generate a narrow "beam" using two identical yagi antennas that share a common reflector. The antennas are oriented about 20 degrees apart with the reflector at the vertex. A near perfect audible square wave drives two identical PIN diode switches on the driven elements. While the antenna may have a -3dB beamwidth of perhaps 10 degrees, the LOP of equal antenna signal levels is extremely sharp, and often less than 0.5 degrees. A synchronous demodulator, charge pump, differential amp, and zero center meter complete the systems. You can also do it by ear by listening to the null at the switching frequency. If the antennas and PIN diode switches are perfectly symmetical, all boresight error

```
cancel.  I originally contrived the system by reading about the Lorenz
beam bombing system used by the German's during WWII, but later
discovered that others had anticipated the idea.

Choice of device seems to be what you're concentrating on but I don't
think the brand name of any device will figure into the solution at
the insurance and electrical code level.

Correct bonding of the equipment ground/RF ground to the house ground
at the entrance panel is the key for any of this. See e.g. W8JI's
webpages.

Tim.

A popular scheme from WJ 30 years ago (at the advent of digital signal
processing) used 3 antennas in a triangle, and basically did
interferometry. Sampling the data and using an FFT lets you do a wide
band at one time (which is handy if you want to DF frequency hopping
radios, which became very popular in the 80s)

As far as VHF, I know a couple here in town I've seen using arrays
for direction finding. But they used four verticals in a square.
It worked quite well. We had one guy that kept jamming one of the
repeaters, and the user of said array was easily capable of tracking
him down to a shopping center parking lot where the guy was sitting
in his car. I suspect the expression on the jammers face when the
tracker tapped on his window was priceless. :)
The device in the car used an array of LED's in a cross configuration
if I remember right.
He had the antenna array on the back of his truck. I don't recall the
element spacing.

Likely a Doppler direction-finder, possibly a Ramsey DDF-1 or one of
the others of that sort.

They aren't perfect... definitely subject to errors due to multipath,
and they works best when looking for a relatively clean, non-modulated
carrier. Fun, though... I've used mine on several occasions to locate
sources of QRM or jamming.

I've seen similar 4-vertical arrays on the roofs of some police cars
in my area. I infer that they're used to track down cars which have
had their Lojack locators triggered, after a car theft.

You are correct with respect to LoJack, which radiates in the high VHF
band. They do pseudo-doppler direction finding. I don't know how
fashionable LoJack is these days... the sophisticated thieves know how
to jam it. The widespread deployment of in-car GPS/cell (On-Star, etc)
covers a lot of the other cases. Face it, most car thieves aren't all

that smart.

Agreed. There are various commerical implimentations. Basically, the
diameter of the "circle" of antennas controls the deviation of the
doppler signal heard on the receiver. The bigger the diameter, that
better the signal to noise ratio. Typical is about 1/2 wave diameter.
Smaller diameters will work, but require narrower digital filters
which slow down aquisition.

>They aren't perfect... definitely subject to errors due to multipath,
>and they works best when looking for a relatively clean, non-modulated

>carrier.

Plenty more wrong with doppler DF. They don't like horizontally
polarized signals. Reflections cause false readings. Forward
alignment (0 degree heading) varies somewhat with frequency. Switching
PIN diodes in the antenna cause interpolation errors every 90 degrees.
Multiple transmitters on the same frequency result in erronious
readings. Antenna tilt causes big errors. Reflections off building
and in particular, the ground ahead of the antenna, causes errors.
There are fixes and work around for most of these, but I haven't seen
any on ham quality dopplers. Some of my ancient comments on the
topic:
<http://www.qsl.net/n9zia/doppler_notes1.txt>
<http://www.qsl.net/n9zia/doppler_notes2.txt>

>Fun, though... I've used mine on several occasions to locate
>sources of QRM or jamming.

Ummm.... How did you get it to produce a usable bearing if there were
two transmitters on the air at the same time? I can see if it you
waited until the jammer was the only carrier, but few jammers allow
that to happen. Mostly we use doppler for the traditional stuck
transmitter.

Mini-rant: Why do almost ALL commerical radios have tx timeout
timers, while almost ALL ham radios don't have this feature?

>I've seen similar 4-vertical arrays on the roofs of some police cars

That's LoJack. I rode around in test vehicle with one trying to make
sense of the indication. In an urban jungle, it's very difficult to
get a decent bearing due to all the building reflections. I suggested
we try an elevated freeway, and the bearings improved. Works much
better in the suburbs.

Is it because we're all known to be gasbags?

Timeout? Why the very *impudence* of that radio!!!

All kidding aside, we had a major repeater outage in San Diego some years ago. A 50w mobile, in the middle of a hotel parking lot, was on the air for hours, holdng the repeater. The T-hunters who found the car ID'ed the owner by his callsign plate and contacted him in the hotel. It was the old microphone-between-the-seat-cushions trick. Timeout would have helped that day.

Yes. That's also why many Japanese ham radios are severely lacking in
microphone gain. I guess they assume that all Americans are always
yelling.

>Timeout? Why the very *impudence* of that radio!!!

Ok, bad choice of a name for the timer. Perhaps "anti-ratchet mouth"
or "monolog restrictor" might be better.

>All kidding aside, we had a major repeater outage in San Diego some years

Yep. It's all too common. My guess is one every month or so. Unfortunately, I managed to jam the microphone under the debris pile that usually clutters the passenger seat, jamming the local repeater. I was easily identified by the classical music in the background since nobody else around listens to classical music. What's really irritating are the number of packet radios that end up on repeater frequencies. Usually, we can decode the call sign and contact the culprit. Occasionally, there's no call sign as the owner is trying to setup his TNC. There's also the stuck transmitter on commercial and public safety frequencies. Those are fun and gets us plenty of points from the various agencies. Extra credit to the local comm shop that likes to defeat the timeout timer, for no obvious reason.

My favorite stuck transmitter was on marine channel 16. There was a very strong carrier on Ch 16, that could be heard all over Monterey Bay. Everyone dug out their DF hardware and the searching began. Strong signal, no modulation, 100% duty cycle. This should be easy. Right...

After 5 days of bad guesses and dead ends, the culprit turned out to be a marine base station on Fremont Pk (3,000ft). It was rarely used and was only functional in order to maintain the license. Something went wrong with the DC wireline control system (with no timer) which stuck it on the air. Why so difficult? The strong signal created a wide assortment of reflections. Everyone had trouble separating the strong reflections from the incident signal with the Doppler DF boxes. I was using my rotating antenna kludge, but stupidly used a 5 element yagi tuned to 146Mhz. At 156.8Mhz, I later discovered that it had almost as much gain towards the back of the antenna as it did in the forward direction.

Incidentally, there's another difference between ham and commercial mobiles. Commercial mobiles have a PL hang up function, where the receiver is in PL decode when the mic is hung in the hanger, and goes to carrier squelch when removed. Many ham mobiles seem to be missing this useful feature.

This is so the commercial operator listen to the whole channel (and not
just his company's CTCSS filtered traffic) prior to transmitting. A
typical ham channel is continuously monitored and everyone has the
same CTCSS tone.

A lot of the jamming in question is jamming of repeaters, so you are DF'ing on the repeater's input frequency.

If you have a rough idea where the jammer is operating, you can often get a Doppler detector (e.g. on a car) into that area and get a decent signal from it when he's jamming... but be far enough away from the person being jammed that you don't hear any of his signal (although the repeater does).

A Dopper rig on the roof of a car has a far smaller line-of-sight radius than a repeater receiver mounted up on a high building or hilltop.

Sure, but we have several other distant repeaters on the same channels

I like to monitor. I also hear plenty of RF leaks and odd sources of RF as I drive around. So, I turn on the PL decode. With a ham radio, I just pickup the mic, the receiver stays in PL decode, and proceed to talk. With the Maxtrac I currently use in the car, as soon as I pickup the mic, I hear all the junk, which helps to make sure I'm not causing a problem by talking over other users on the distant repeaters. (We have somewhat overlapping coverage areas). Also, when in PL decode, there's about a 600msec delay before the rx squelch opens, which obliterates the first two syllables.

It does not seem the public safety radio devices always had this timeout timer either.

Before the public safety services here switched to a digital system,
they used NBFM equipment from companies like Motorola, and it was very
common to hear stuck transmitters that blocked an entire repeater channel.
(which often consists of multiple receivers and transmitters over a city area)

Police used mobile transceivers in the cars on VHF and portables on UHF
so it usually was possible to alert the users on the other channel and
hope the stuck PTT key was found that way, but on major events like
queen's day it often happened that the portables channel was jammed for
half an hour or so before the culprit was found.

Of course the equipment was aging by that time, it probably was from
the eighties. Now they are all on TETRA and AFAIK that system allows
the operator to just tune out stuck transmitters or devices that fell
into wrong hands.

Methinks that just about every radio, by Motorola and Kenwood have a transmit timeout timer.
<http://802.11junk.com/jeffl/pics/drivel/slides/too-many-radios.html>
The dip switch programmable radios (SP10) do not have a timer, but literally every radio that requires a computah to setup has a timer. Note that I was talking about mobile radios all of which are programmable, not handhelds.

>Before the public safety services here switched to a digital system,

>(which often consists of multiple receivers and transmitters over a city area)

That's a programming issue. The timer is off by default and must be enabled and set for a specific number of seconds. 60 seconds is the typical timeout.

Digital radio comes in many flavors. One of the big advantages of digital is that the repeater and channel can handle more than one transmission at a time (either by TDM or FDM). Therefore a stuck digital transmitter does not timeout or disable the repeater. In addition, many such radios are full duplex, which allows the dispatcher or comm shop to remotely disable the transmitter and yell at the user. Whether the PSAP is setup and trained to do this is debatable.

>Police used mobile transceivers in the cars on VHF and portables on UHF

Yep. Simply identifying the stuck transmitter is often insufficient. I've heard stuck transmitters in vehicles rolling down the freeway for an hour with a stuck transmitter. It was obvious who it was but nothing short of an RF seeking missile was going to get their attention. In one case, someone noticed that they were listening to specific local radio station. The dispatcher called the radio station and had them make a special announcement to the driver to unstick the transmitter. It worked, instantly.

>Of course the equipment was aging by that time, it probably was from

Yep. Nice feature. In the US, the high end radios are P25. Various
other narrow band solutions exist, most of which have remote
programming and remote deactivation. Despite all the government
programs intended to provide interoperability, the manufacturers (and
the FCC) have gone out of their way to introduce proprietary
enhancements and introduce intentional incompatibility.

Why I cannot get rid of that antenna I dunno,
all started because I could not get the PVC tubing which the many
internet sites propose. The plumber shops where I live can only supply
heavy massive material suited as killing weapon in the hands of a
desperate fox hunter.

So I had to look for an alternative design and that lead me
to the aluminium boom with the movable slider.

The most exciting discovery during the work was
that every boom has two ends.
You correct me if I am wrong.

Hmm, cue someone yelling "Yo mamma's so fat the antenna in her pants is resonant on the 2200 metre band!"

I could see this antenna concept working for UHF and above. Especially if they could make the other components "sewn in". i.e. perhaps a hooded top or cap with Bluetooth headset embedded. More likely such designs would be used to provide a level of shielding from the wearer, so I suspect any such antenna would behave like a typical patch antenna, with a radiation pattern being away from the body.

Even then though, it'd probably be a bit gimmicky.

This got a mention in the WIA news service a few weeks ago:

THE QNEWS WORK BENCH - the nuts and volts report -
(Measure twice - Cut once!)

BAE Systems tests T-shirt antennas

Wired reports that BAE Systems have teamed up with the UK's National Physical Laboratory to measure the efficiency of radiation emitted from wearable antennas embedded into T-shirts.

Wearable antennas could be a useful way of building communications networks in warzones or of monitoring and transmitting the health of the wearer.

Given that they are worn on the body, it is particularly important to understand their performance. The human body absorbs electromagnetic signals so researchers were concerned that the signal could lose power if worn too close.

This concept has been around for at least 10 years, maybe more.

As you note, meeting the RF exposure limit is one of the challenges. However, spreading it out helps. the typical limit is somewhere around a few milliwatts/sq cm. So say you wanted to radiate 10 watts. If you can spread the antenna out over 0.1 square meter, then you're at 10mW/sq cm, and by the time you add some shielding and/or consider the duty cycle, you can stay below the limit.

(hey, better than putting an antenna 10cm long radiating 2 Watts next to your head, eh?)

Figuring out how to control the pattern is another.

One scheme (becoming more practical) is to make a phased array of sorts, with distributed switches throughout the fabric to turn segments on or off or change L/C loading.

Hams, at least in the US, tend to ignore all the rules about RF exposure (notwithstanding it's on the test, etc.).   You see pictures of whip or loop antennas clamped to picnic tables next to the operator or mag mount antennas stuck to the top of a "go box portable station" with a 100W rig.

yes, they're probably meeting the limit, once you take into account the duty cycle, etc., but I'll bet less than 0.1% of them have actually done the analysis to prove it. The typical response is "I've been doing this for years and I've never noticed any problem"

Not to mention that the safe harbor "assumed safe" limits only apply with "single transmitter".. and that's not just ham transmitters, so the cellphone on your belt qualifies as the second transmitter triggering the need to do the analysis.

So, I'm waiting for the QST article with the guy having a backpack SGC500 power cube driving their 20m wearable antenna.

Is this safe? I'm not allowed to exceed so many mW/meter at several
feet. I guess it depends how the current is distributed.
****
-
My thoughts immediately were that with all the hype about cellphones causing

brain tumors, sterility, and perhaps herpes....that it is surprising that anyone would be proposing wearable antennas.

However, these antennas have been around for a few years, in applications such as "black" projects.

It will never take off for the general public for the simple reason that
what people wear is dictated by fashion, not cell phone reception.

The only place you will ever see such is in applications like military,
police, fire, etc. where having communications (other than cell) is part

of the job.

She should like that. I'm usually going off somewhere, then running into
her disapproval when I return. It'll keep me close.

People in those situations are paid to take some amount of risk (sort of
like working as a firefighter or nuclear worker)

If this is your opinion you can't evaluate hardware worth bleep.

The majority of what they sell does exactly what it's advertised to do. You have to read the specs. And read the reviews carefully because the hams who post that can't make the items work are often just ignorant or incompetent.

It is not the best available, but it is often good enough.

You can call them up and complain directly to the designers. Try doing
that with Rohde and Scrwarz.

Right, now start with the rest of the memes...

Rat Shack, ePay etc.

Until I see you selling the same products as MFJ,
at a higher quality and lower price, I don't wanna hear it.

Jeff

Generally true. However, I spent some time modeling the MFJ-1800
2.4GHz antenna and came the conclusion that it's not even close to 50
ohms and more like 300 ohms. I guess they forgot to include a balun:
<http://www.mfjenterprises.com/Product.php?productid=MFJ-1800>
<http://802.11junk.com/jeffl/antennas/mfj1800/index.html>
While one screwup is not sufficient to claim that the entire product
line is lacking, it does make me very suspicious and wary.

>And read the reviews carefully because
>the hams who post that can't make the items work are often just ignorant
>or incompetent.

True. Everyone that disagrees with me is automatically judged to be
incompetent, ignorant, or both.

MFJ-868 shows 21 reviews, most of them positive.
<http://www.eham.net/reviews/detail/6459>
The ones with critical reviews were either failures of some manner, or
what I attribute to calibration issues. Looking at the schematic at:
<http://www.mfjenterprises.com/pdffiles/MFJ-868.pdf>
methinks it's "good enough". I'm not thrilled by the design, but it
does have an integrating RC networks, with a 2 second time constant,
which would make it peak reading.

QST compares various wattmeters:
<http://www.palstar.com/qstWM150.pdf>
Unfortunately, the MJF-868 is not reviewed, but the article might
offer some clues as to what to look for in a wattmeter.

That's a pretty harsh statement there pal.I bought and used one of the
antenna tuners the proclaimed as "up to 300 watts" and the friggin'
4:1 balun blew out after 2 days of usage.I bought the contraption cuz
I didn't have the time or parts to build a really good one myself at
the time.
You really want a decent tuner do yourself a favor and take the time
and build one.Just google the K1JJ super tuner ,you'll thank yourself
and be a lot less lighter in the wallet for it.

>
> It is not the best available, but it is often good enough.

What a sales pitch.

I'm curious, did you do any measurement and testing with an analyzer, etc., or
are all the figures simply calculated estimates?

Has anyone confirmed what the piece is that connects the driven element with the
coax connector that looks to be a short piece of coax covered in heat shrink?
Has anything been found or measured hiding under the heat shrink?

I realize we can all assume the antenna impedance is 50 ohms, but is it actually
stated in any of the specifications from MFJ? I didn't see any mention of
impedance specification at all for this antenna, but I could only find
information on the web page at the link you provided as well as in the pdf file
of the instructions for the MFJ-1800. The instructions are rather sparse.

Thanks for taking the time to provide details.

BTW, Irene's knocking at the door!

73, Renee

So that means every company that makes any product that has a problem after two days is making junk? That's everyone BTW.

My second analyzer hasn't had a problem at all.

I've a 949 tuner - FB

I have a 993 auto tuner - never had a problem with it.

Now it is true that MFJ in general does not have the build quality of some of the "better" units. It also doesn't cost anywhere near as much. And their return policy is more generous than most.

And what to we get for this? I've put my analyzer up against some pretty expensive units, and they all have similar problems with overload. And given the price difference, I wouldn't be able to afford the more expensive ones. So is it better to buy the "Mighty fine junk" or to do without?

They actually perform a service to the amateur community. If you're too good for MFJ don't buy their stuff. But you might have the grace to not lord it over us lesser beings.

At one time I was working JA from yhe UK using a long wire (about 40m) of 30 swg and 100w. It didn't blow down. however it was only up for a week as a stealth ant. currently my long wire is 1mm enameled wire, to be less vu=isibly intrusive (and at current copper prices cheaper) than the recommended 14 swg (12 awg).

This replaces one which failed a couple of years ago constructed with thin insulated 5A lighting flex not much more than bell wire that had been up nearly 30 years.

It's better using a non optimal stealth ant than none at all!

I used 10mm resin anchors for a similar installation into brick, they have
the advantage of being less likely to crack the brick as compared to
expanding/rawl bolts. Breeze block is a dubious material, depending on it's
strength it may or may not be ok. If it is a dense concrete block you should
be ok, but I'd recommend resin type anchors anyway. I got mine from screwfix.

>
> You have a point Mark. I agree that a simple 1/4 wave groundplane is more study and very easy to make using an so-239 and some piano wire. Steel wire can be soldered right into the back, four bolts with nuts and four more peaces of wire around 19" long with a bit of a downward bend and you have a very good antenna.
>
> Kevin, WB5RUE
>
>

I'd use copper wire vs the steel or piano wire. They would work, but I think the copper would be a better conductor. Steel in particular is not too good. Also copper is a lot easier to solder to. If you use solid wire of say 12 or 14 gauge, it's stiff enough to stand up straight, but flexible enough to be bent and hold it's shape.

If you are going to hang the antenna from something, you can use the inner conductor of coax as the radiator, "shield stripped back 19 inches" and attach wire radials to the shield. All you have to do is hang it up, and then bend out the radials at about 45 degrees, and you are ready to become radioactive.

For a deluxe version, shave off the covering of the braid a 1/4 wave below the radials at the feed point and add a second set of radials to the braid.

That version would be well decoupled. Would blow most J poles out of the water I suspect if you want to concentrate on the horizon, vs up at some peculiar angle which is fairly useless for VHF/UHF.

Decoupling of the feed line is more important than radiator gain on those bands. IE: a 1/4 GP can often outperform a 1/2 wave vertical if the 1/2 wave has little or no decoupling. Which is the case for most

1/2 wave J poles.

NFPA (according to what you posted) requires heavier gauge wire for
transmitting than for receiving. Transmitting makes the wire weigh more?

Funnily enough I was just looking into chemical (resin) fixings - do you have a link for the screwfix anchors you used ?

I have in the past used rawbolt's and indeed split the wall, well the ones near the top, a low thump as I tightened them up. They seemed ok with no problem afterwards with a 2m 10XY and a 88ele 70cm beams (this was my mum & dads house!)

It's worth noting that you don't actually need four radials. Two radials (on opposite sides of the feedpoint, bent down at around 45 degrees) will produce a perfectly satisfactory ground-plane. The patterns of 2- and 4-radial ground plane antennas are almost indistinguishable. A 4-radial antenna may *look* as if it would produce a much more circular pattern than a 2-radial antenna, but this doesn't turn out to actually be the case.

I'm in a 1960s neighborhood. If anybody bitches about antennas (nothing, yet), I will invite their attention to the old-fashioned utility poles & wires that decorate (?) the streets. A few blocks out and a few years later, they undergrounded the utilities.

Sal

This got me thinking. (Dangerous, yes, but I occasionally risk it.)

Since a normal dipole has current max near the center, is there more localized heating (I-squared-R) nearer the feed point? Seems like it ought to be. Can you overheat a small wire and make it fail there by melting?????

No, I don't want to try it. I'm hoping somebody knows. Exciting story even better.

My only time to be arrested in 68 years:  Paris, early afternoon, public
park, sober, in USN uniform.  Have all the fun you want with jokes at their
expense.

Eskimos have over 60 words for "ice."  The French have about that many for
"surrender."

OK, I'm done.

That's true as far as the pattern. But.. The more radials you
use, the better the decoupling from the feed line. Most of my
1/4 wave GP's actually use 6-8 radials. I've done tests, and
it does make a difference. But for casual use, what you say is
true. Only two radials are required to get a pretty good omni
pattern. Or one, if vertical.. But then you might as well call
it a 1/2 wave vertical instead of a ground plane.
And you will then require some kind of decoupling scheme below
the vertical for optimum results. I prefer radial sets, cones, etc
vs feed line chokes.

> Anyone have experience making a dipole from 18 gauge speaker wire? I have a whole lot of it lying around the house, and was wondering if I could put it to some good use.

Be aware that the National Electric Code (NEC); that is enforced as law in many jurisdictions; forbids the use of wire that small for aerials of radio stations. The NEC specifically requires that size fourteen American Wire Gauge be the minimum size that is used.

In point of fact you are unlikely to ever get inspected unless some neighbor is raising a stink about your antenna. The danger is that in the event of a physical failure of the antenna that brings harm to anyone or anything, the use of non code compliant size wire will shift all blame on to you. That could include a trespassing neighbor kid yanking on your coax lead in and being burned before you realized that the antenna was in direct contact with him because the wire of the antenna that was supporting the coax had failed. The reason that you might be blamed for something that at first blush appears to be outrageous conduct on the kids part is based on the idea that anything like that which is not sufficiently guarded so as to prevent that kind of occurrence is considered to be an attractive nuisance in the eyes of the law.

If the wire is supported on a messenger that has at least the breaking strength of #14 AWG wire the reasonableness standard should serve as an effective shield against that particular approach in a law suit. Be aware that in electrical parlance, which is what the code is written in, messenger supported means that it is continuously supported by another means. It does not mean that it is suspended from some stronger support at it's ends. To be messenger supported the entire weight and the catenary strain of the support system would have to be born entirely by a means other than the undersized conductor itself.

I am not a lawyer nor do I play one on local cable access television. If you need advice about the most likely legal affects of an injury that is caused by your amateur radio equipment you might want to patronize a law schools legal clinic. The Professors that supervise such clinics love questions like this because they take a fair amount of effort to answer well. What you end up with is really high quality advice prepared under the supervision of some of the best legal minds that a person of ordinary means could ever get access to.

I've quoted the sections of the NEC which are applicable to antenna conductor size below. Be aware that the NEC contains many more provisions covering amateur radio stations specifically. It is worth your time to obtain the use of the edition of the NEC that is adopted for enforcement in your community and check your installation against the provisions of the code.

Tom Horne, W3TDH

"ARTICLE 810 Radio and Television Equipment

I. General

810.1 Scope.

This article covers antenna systems for radio and television receiving equipment, amateur radio transmitting and receiving equipment, and certain features of transmitter safety. This article covers antennas such as multi-element, vertical rod, and dish, and also covers the wiring and cabling that connects them to equipment.

810.11 Material.

Antennas and lead-in conductors shall be of hard-drawn copper, bronze, aluminum alloy, copper-clad steel, or other high-strength, corrosion-resistant material.

Exception: Soft-drawn or medium-drawn copper shall be permitted for lead-in conductors where the maximum span between points of support is less than 11 m (35 ft).

810.12 Supports.

Outdoor antennas and lead-in conductors shall be securely supported. The antennas or lead-in conductors shall not be attached to the electric service mast. They shall not be attached to poles or similar structures carrying open electric light or power wires or trolley wires of over 250 volts between conductors. Insulators supporting the antenna conductors shall have sufficient mechanical strength to safely support the conductors. Lead-in conductors shall be securely attached to the antennas.

810.13 Avoidance of Contacts with Conductors of Other Systems.

Outdoor antennas and lead-in conductors from an antenna to a building shall not cross over open conductors of electric light or power circuits and shall be kept well away from all such circuits so as to avoid the possibility of accidental contact. Where proximity to open electric light or power service conductors of less than 250 volts between conductors cannot be avoided, the installation shall be such as to provide a clearance of at least 600 mm (2 ft).

Where practicable, antenna conductors shall be installed so as not to cross under open electric light or power conductors.

[One of the leading causes of electrical shock and electrocution, according to statistical reports, is the accidental contact of radio, television, and amateur radio transmitting and receiving antennas and equipment with light or power conductors. Extreme caution should therefore be exercised during this type of installation, and periodic visual inspections should be conducted thereafter.] This is explanatory material from the NEC Handbook and not part of the NEC.

810.14 Splices.
Splices and joints in antenna spans shall be made mechanically secure with approved splicing devices or by such other means as will not appreciably weaken the conductors.

[Conductor spans from antennas should be of sufficient size and strength to maintain clearances and avoid possible contact with light or power conductors. Splices and joints should be made with approved connectors or other means that provide sufficient mechanical strength so that conductors are not weakened appreciably, a condition that could cause them to break and come into contact with higher-voltage conductors.] This is explanatory material from the NEC Handbook and not part of the NEC.

810.15 Grounding.
Masts and metal structures supporting antennas shall be grounded in accordance with 810.21.

810.52 Size of Antenna.
Antenna conductors for transmitting and receiving stations shall be of a size not less than given in Table 810.52.

Table 810.52 Size of Amateur Station Outdoor Antenna Conductors

Material	Minimum Size of Conductors (AWG) Where Maximum Open Span Length Is	
	Less Than 45 m (150 ft)	Over 45 m (150 ft)
Hard-drawn copper	14	10
Copper-clad steel, bronze, or other high-strength material	14	12

810.53 Size of Lead-In Conductors.
Lead-in conductors for transmitting stations shall, for various maximum span lengths, be of a size at least as great as that of conductors for antennas as specified in 810.52." Copyright 2002 the National Fire Protection Association.

No but it does make it more dangerous to persons and things on which it
might fall if it breaks.

```
>to be.  Can you overheat a small wire and make it fail there by melting?????

Yup.  The amount of current that would do that is called the "Fuse
Current" which can be dramatically large.  Example, wirewrap wire's
fuse current is slightly more than 10 Amps.

And of course, there are hams out there who consider the NEC, as applied to antennas on their own property, to be an irrelevant government overreach.

Naturally, that is not my opinion :)

Come on, Guys!

While it's a great idea to follow every official code and reccomendation, and that no one in their "right mind" would ever consider anything less than the lowest gauge copperweld wire for their antenna, the original question is answerable by "Yes, you can make a serviceable antenna out of speaker wire."

Will it stay up as long as a Copperweld antenna held in place by1/4 inch thick 100 percent nylon rope?

No it won't.

But it will work. Surprisingly well, in fact.

Let the new guys learn, and throw up antennas that work. As they have to put up a new one every so often, they will eventually learn about more long lasting antennas, as well as ones that might have a better pattern, and other effects that bear on performance.

But the idea that hams are responsible for restrictive covenents (in reality, Cable television is more responsible for antenna covenants than anything else) or that the choice of speaker wire is going to electrocute the neighbors is doing a disservice to the new guys and gals.

I can say this with some conviction because I was one of those noobs once, and nearly didn't even get on HF because with all the input, I gave up on putting up an antenna because nothing was good enough. I didn't have enough space, I didn't have enough height. There just wasn't any use in getting on the low bands. I needed a separate antenna for every band because ladder line was awful and traps were bad and every other option was awful except for some idealized correct antenna, coax fed, at the proper height.

I have found that the safest option is to not ever put up any antenna whatsoever, Tom. It's just too dangerous, and gives us unneeded exposure.

Can you ensure that an antenna that is installed to the code specifications, will not fall down?

Will your code spec prevent you from incurring liability if a wire antenna falls down and electrocutes a neighbor?

The answer to both questions is "no", BTW.

I find that this entire discussion is pretty amazing when compared to the original question.

As opposed to electrical code and liability admonitions, perhaps a good answer is:

"Yes, you can make an adequate antenna from speaker wire. There might be better options, though."

I've found that when I attempt to speak the language, I'm pretty well treated.

Now there is the possibility that they just find it amusing and charming, because I took both French and Spanish, and in conversation I can slip between both languages inadvertently.

Usually when I note that I "Parlez poco Francaise" they start smiling....

As for New York, I haven't had much trouble there, but then I give back
what I get. Most seem to actually like some attitude. Go figure!

Like the old joke "Can you tell me the directions to Soho, or should I
just go @*^! myself?

Whaddevuh! 8^)

Thanks, looks cheaper than Screwfix. Did you use a normal 'frame' with the
resin, I think some of them need a stronger frame because of  the viscous
nature of the resin. Looking at the spec this resin is really strong stuff I
didn't realise how strong it was - about 2800Kg tensile strength on a 10mm
bolt !....

```

On Tue, 02 Aug 2011 23:11:33 -0400, Mike Coslo rearranged some electrons to say:

> But it will work. Surprisingly well, in fact.
>

My present HF antenna is a piece of 4-conductor ribbon cable, with 60 feet of each outside conductor pulled off to make a 120 foot dipole, the rest of the cable being used as a feedline to a balun and thence to a tuner. Is it ideal? No. But it's good enough to work 45 states so far on 75m, a few dozen DX contacts on 20 and 40m, etc. Plus, it's nearly invisible against the side of the house.

During field day, I used a homemade doublet fed with 450 ohm ladder line to the same tuner, remotely mounted in a waterproof box, I was able to work 15m and 80m on the same antenna, made a few hundred contacts. Eventually (when the leaves fall) I plan to replace the ribbon cable dipole with the doublet and the remote tuner on some tall trees in the backyard.

Very simply, yes, it can be used for making antennas. If it's strong enough to hold up it's own weight, and that of the feed line without stretching unreasonably, then it should do fine. What happens if it stretches? You shorten it. I think I'd try a larger size for 160 meters and maybe 80 meters, but if it can stand the weight and the weather, why not?

I have a Heath HM-2102 VHF SWR power meter 50-160 MHz
0-25 and 0-250 watts. Excellent condition.

I'm *asking* $40 plus shipping.

It can be viewed at:

http://home.comcast.net/~hsknoll/site/?/photos/
&PHPSESSID=29ec62ea0bf1fe4d25e318b011cf0bbf

or

http://tinyurl.com/yktwxpz   click on photo to enlarge it.

If you hang on to it a little longer it will be a 'classic' and you can ask more for it!

In actuality, things like that are available at a lot of ham flea markets, and in some cases, hams will give you things like that just because they are 'real' hams.

Right.

But I would like to say that it isn't at all that the information is wrong. In fact, the experts are generally 100 percent right. And that is where some of the problems are.

A noob comes in, and gets 3 different answers, and becomes hopelessly confused because they would seem to contradict each other. They don't really know how to figure it out.

It isn't confined to this group. Another group I'm in where I am a bit of an expert, Amateur telescope making, some times suffers from the same thing.

My point is that I'm not trying to chide the experts. After all, it's not very graceful to bust peoples chops when they take the time to answer a question. I's more begging them to realize that I'm a bit of an idiot, and easily confused!

Yes.

I have properly-built 6m jpole which terminates in my shack. If I disconnect the coax from the 6m rig, the connector center pin fits nicely into the LONG WIRE terminal on my HF tuner.   Electrically, the antenna is merely a 13' hunk of metal, untuned as far as HF is concerned, except after a little tuner knobulation.   It's not the equal of a 'proper" antenna, but it works.

If this meter is still available, I'll take it.

SS is a terrible conductor?

I've seen copper clad MIG wire

The real issue is either you're putting that antenna up for the ages, in which case the NEC (aka NFPA 70) rules are a good sizing guideline; or, you're putting it up expecting it to fall down sooner or later, in which case you might as use whatever wire is convenient. For a lot of folks, buying a 500 foot spool of solid AWG14 wire at the hardware store is a good compromise.

The real issue is paying attention to "what happens when the wire breaks" so that you don't wind up inadvertently connecting the 14.4kV MV distribution line to your hand via the feedline and rig.

An interesting observation. You'd have to go look at the history of
that article in the code to find out why. It's not impossible that they
were following standard commercial installation practice/recommendations
back in the day, and it was "acceptable power loss" related. (the wire
sizing for AC branch circuits is based on tolerating a 2% voltage drop,
not overheating of the conductor)

Fusing current is remarkably high for small conductors in free air, even for 100% duty cycle.

AWG30 (0.01" diameter) = about 10 Amps (Preece equation)

Scales as 1.5 power..
so, going to AWG 20 (.0316") -> about 50 amps..

Considering an inverted V dipole with feedpoint Z of 50 ohms, at 1kW, the current is about 5 amps...

So running that legal limit amp with a brick on the key to your AWG30 stealth antenna won't melt it. (it probably will get pretty warm.. and corona at the ends might be spectacular)

I was thinking more of local codes or enforcement. After all, the local
"Authority Having Jurisdiction" (AHJ in code-speak) can and does
override the NEC all the time.

There are also a whole lot of other "installations of a temporary
nature" in the code: check out the sections about theatrical and motion
picture filming. They allow substantially higher currents for a given
size wire, on the not unreasonable basis that they're being operated
under the (hopefully) continuous supervision of qualified personnel.

Xref: g2news1.google.com rec.radio.amateur.antenna:22241

I'm a neophyte here, but I've done quite a bit of reading on antenna characteristics and design. Still, I'd appreciate some advice from the more knowledgeable (that's pretty much anybody here).

1. I have pretty limited options for a serviceable antenna for, say, 40 to 10 meters. Right now, I am interested in CW only using QRP rigs (homebrew) for DX QSO's.

2. I want to limit the visual impact, so unless you advise strongly in favor of them I want to avoid verticals. I don't have code or covenant restrictions, but I do have a wife.

3. Here's the physical situation: My suburban property has two houses on it but no real trees I could use as anchor points. However, from peak of the big house to that of the guest house I can get about 96 feet. The big-house peak is about 25 feet high and the guest house about 13. For visual purposes, I'd like to use as thin a wire as possible.

4. Here's my idea: an end-fed wire with traps for multi-band use. I don't see how I could use a center-fed dipole unless the feeder came back parallel (right next to) along one leg of the dipole. In other words, I can't feed at perpendicularly. For a variety of reasons, the azimuth of a wire line between the two houses would be about 25 degrees/205 degrees.

So . . . what do you think? What kind of performance do you think I could expect from this setup?

Many thanks! ---Todd

It was a lot like that in Germany in the 80's .I was stationed there
for 3 years and found if you get out of the "GI Towns" and went to the
smaller villages and towns outside of the bases they treated you like
gold.Of course I guess that's like anywhere else you get out of the
big cities and people are a more laid back .

[Sorry if this is a repeat post. The first didn't seem to go through.]

I'm a neophyte here, but I've done quite a bit of reading on antenna characteristics and design. Still, I'd appreciate some advice from the more knowledgeable (that's pretty much anybody here).

1. I have pretty limited options for a serviceable antenna for, say, 40 to 10 meters. Right now, I am interested in CW only using QRP rigs (homebrew) for DX QSO's.

2. I want to limit the visual impact, so unless you advise strongly in favor of them I want to avoid verticals. I don't have code or covenant restrictions, but I do have a wife.

3. Here's the physical situation: My suburban property has two houses on it but no real trees I could use as anchor points. However, from peak of the big house to that of the guest house I can get about 96 feet. The big-house peak is about 25 feet high and the guest house about 13. For visual purposes, I'd like to use as thin a wire as possible.

4. Here's my idea: an end-fed wire with traps for multi-band use. I don't see how I could use a center-fed dipole unless the feeder came

back parallel (right next to) along one leg of the dipole. In other words, I can't feed at perpendicularly. For a variety of reasons, the azimuth of a wire line between the two houses would be about 25 degrees/205 degrees.

So . . . what do you think? What kind of performance do you think I could expect from this setup?

Many thanks! ---Todd

MFJ claims that some of its products indicate PEP on SSB telephony, and some of the claims are plainly fraud.

In my experience, if the instrument does not use an active 'sample and hold' amplifier, it does not work adequately.

In the MFJ949E tuner, the PCB has provision for a single transistor amplifier, which if fitted, works passably... but they do not populate the board with the 20c worth of parts needed.

The good news is that the MFJ868 does have an active PEP amplifier, it looks a similar circuit to that in my AL80B which does work quite well. I have not checked the circuit in detail, nor the time constants involved, but this has a chance of working and working well.

> Is it really a true peak reading meter?

Well, of the MFJ949E, MFJ says "Lets you easily read SWR, true peak forward and average reflected power simultaneously on 300 Watt or 30 Watt ranges", and let me assure you that their "true peak forward" is a fraud... so this claim questions MFJ's credibility.

Don't trust any advertising claim with the word "true" in it.

BTW, the reflected meter in the '949E does not read average power of SSB telephony either, both meters can read the average power of an unmodulated wave.

Sellers make extravagant claims to a tame market that mostly doesn't understand the technical side.

Try an off-center fed dipole (OCF).

Here's what I use:
http://www.wcerc.org/Projects/ocf_dipole.asp

Here's the balun I use:
http://www.balundesigns.com/servlet/the-75/OCF-balun-4-cln-1/Detail

I am a QRP CW operator with no trees on my property. I run a Small Wonder Lab SW-40 (1.5 watts) and a Yaesu FT-817 at 2.5 watts. The balun is tied to a PVC vent pipe on my roof, about 25 feet in the air. The long end of the antenna goes to my shed and terminates about 15 feet above ground. The short end runs to my garage and terminates about 12 feet above ground.

The antenna loads on 80 but the bandwidth is very small. Works fine on 40 -- with my QRP rigs, I work into Europe, S America, Caribbean, Canada, all over US, occasionall into South Pacific.

Here is a commercially available OCF dipole:

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been
recently revived by an active moderation team.  We are currently seeking
suitable information, FAQ, and bulletin articles from the entire
rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our
newsgroup.

We are seeking a replacement maintainer for the following information
bulletin formerly posted to rec.radio.amateur.* (and currently archived
at http://www.faqs.org/faqs/radio/personal-intro/ ):

 radio/personal-intro
 Subject: Guide to the rec.radio Newsgroups

I was offered (for free) a VHF TV yagi anntena w/ rotor. Question: would
this work a 2M antenna? With a tuner, maybe?

I'm inclined toward OCF also. I ran one for a while, which worked out well because I could run the feed down to the shack window right at the short side of the thing. I'd suggest a tuner as well. They do tune okay, but the tuner extends the useable frequencies. Also, my antenna was marginal at 20 meters. OCF isn't the "ideal" antenna, but you could do a lot worse.

Only if you modify the yagi to resonate on 2 metres.
Here is a link that will help you:

http://www.arrl.org/files/file/Technology/tis/info/pdf/9611034.pdf

The article on the TV to 2m conversion is on the ARRL Technical Info site:

http://www.arrl.org/tis/info/Yagi-V.html

It is a copy of the original article from QST magazine, and is only

```
available to ARRL members from that source.

Agreed.  Forgot to mention that I use a tuner with mine.

I have an old ICOM IC-729 with the companion AT-150 tuner.

A while back I asked about experiences on the group with verticals on
metal patio covers.  Today I had a chance to run an experiment that
turned out fine.  There is a lot of conduit above the cover for fan,
2 outlets, and 6 lights.  I used a mobile antenna roof rack mount on
a section of conduit and mounted an Outbacker mobile antenna.

Twenty meters was the only band tryed, and results were OK.  Best of
all, the antenna received approval by "she who approves things".
Next step is to put up a longer radiator without loading coils.

Yes, it will work. I just tried it with my HT. From southeast of San Diego, I raised a repeater on Mt. Santiago, Orange County, with a 75-ohm directional VHF TV antenna and a half-watt signal. Santiago is 70 miles away. Disclaimer: My location, on a small hill with a generally clear view toward the North, gives me an advantage.

Then, I put the analyzer on that antenna and I was surprised to find the 2m VSWR was 3.1:1, worst case. Losses through about 50' of cable from here to the antenna no doubt helped my VSWR number.

There is some risk of using it with a high-power rig if the rig isn't internally protected against operating into an excessive VSWR. Most are.

Start at a modest power and see what happens. That's what a lot of hamming involves ... try it and see.   Smoke is possible but not common.

Take it before they change their mind!
The rotor is a definate yes and 2 meter antennas are about as easy as
it can ever be with building antennas!

My 15 year old son is exploring shortwave radio, and has purchased a Realistic DX-394a. We're experimenting with various antenna configurations, now trying an inverted L. The layout so far can be seen at:

http://i258.photobucket.com/albums/hh242/winwinsit/antenna2.jpg

So, a single strand wire crosses the yard at a height of about 14-18 feet, stretched east-west, insulated at each end, and another length of wire connected to it drops to below a window, then passes through the wall and to the Hi-Z antenna input. (The diagram shows a lightning arrestor, but that isn't attached yet.)

But it seems to offer little or no advantage over the little telescoping antenna. In fact, the best reception is when we touch the antenna lead wire to the telescoping antenna. Do you suggest:

1) an antenna tuner?

2) coaxial cable running from the radio (Lo-Z input) to the end of the 75 foot run?

3) a north-south run?

4) a completely different configuration?

5) anything else?

St. Bernadette says,
"And now as I stand Here in the Heavens with The
Beloved Mother, with The Divine Holy Trinity, I am

allowed to speak to you to help you come Here. The purpose of this Great Miracle is to teach you God's Way, to give you firsthand, His Wisdom, His Truths. So, I repeat to you what The Heavenly Mother once said to me: 'Walk in modesty, walk in purity, walk in obedience, walk in trusting God alone, walk in a true love and not an imaginary one."

REVELATION DELIVERED THROUGH FRANCES M. KLUG ON MARCH 18,1972- EVENING

SAINT BERNADETTE

"My beloved children, I am Saint Bernadette and I come to you on this night for a special reason. When Our Lady appeared to me when I was in the world, She stressed purity, She stressed modesty, She stressed truth and She stressed self-discipline, and She stressed doing all things God's Way and in His Will. And now, as I come to you on this night through a child as you, time is repeated, and there are similarities here as I speak to you.

Many men said that my Visions could not be true. I knew they were, for you see, when Our Lady spoke to me, She spoke of the Divine Beauty of Heaven. And I knew, the manner in which She spoke, the feeling I had when She spoke, the sight I saw with my eyes, could not have been imagination nor man. I carried the beauty of this all through my life and when my physical time was about to end, I did not feel pride in having seen what I had, but I felt a great desire to do all I could to help other men.

And now as I stand Here in the Heavens with The Beloved Mother, with The Divine Holy Trinity, I am allowed to speak to you to help you come Here. The purpose of this Great Miracle is to teach you God's Way, to give you firsthand, His Wisdom, His Truths. So, I repeat to you what The Heavenly Mother once said to me: 'Walk in modesty, walk in purity, walk in obedience, walk in trusting God alone, walk in a true love and not an imaginary one.'

I bless you with God's Love and I say, 'Hold tight to the Holy Rosary every day, and when you do your Heavenly Mother loves you.' So be it."

Check for a slide switch on the back that switches from internal to
external antenna.

Cheers,
John KD5YI

I found the manuals and the schematic online but I still need to engage in guesswork.   Work with me.

You said best reception is obtained by touching your lead-in to the telescoping antenna. Would you believe there is one and only one component betweent the ANT HI-Z jack and the termination of the telescoping antenna? it's a15 pF coupling capacitor. I guess it's bad .

Its reference designation is C179. There is another component in the circuit, a 100K static drain resistor, R190, connected to ground. Resistors rarely short out, so I won't guess that; besides, if it were to short, it would hamper reception with the telescoping whip.

Connecting your outside antenna to the telecoping whip with a clip lead may be OK, now and forever. I'd like to see you do it through a 15 pF capacitor, if possible. This project/repair may end here.

If you want to proceded with troubleshooting, connect your antenna to the ANT HI-Z jack. Open the case and move the body of the ANT HI-Z jack while listening. Wiggle it gently. The solder joint to the PC board may have cracked. I've seen about six of these failures with consumer equipment. Sometimes an easy fix, sometimes a PITA.

If you can locate the junction of C179 and R190, touch your antenna lead to that point instead, still while listening. There is no voltage there and you can't be hurt. (It's like touching the telescoping whip, actually.) R190 is a few milimeters in from the ANT HI-Z jack on top of the board. It's an easy reach. I can't tell you which end is which. If you touch the ground end first, nothing will happen, if you touch the correct end first (and the ANT HI-Z jack is bad) you will hear signals. If you don't hear them, it's probably C179 that's bad.

Maybe I've gone too fast and confused you. Read it again and/or get back to me.

I guess one other option is to try your other connection for an external antenna, labeled "ANT LO-Z". What does that do for ya? If you were to change your antenna to a coaxial-fed dipole, the ANT LO-Z would probably be a good match at most frequencies. If you are already "experimenting with various antenna configurations," you ought to try that one, too. The attenator switch, ATT 0dB - 20dB, is in-line with that path; work the switch a few times to be sure it's free of corrosion enough for good contacts.

Feedback to me would be nice. A Nobel Prize would be a bonus.

I would suspect that if you simply touched the same place with your
finger (no antenna then either) you would get "the best reception."

>Do you suggest:
>
>1) an antenna tuner?

Very much suggested, yes.

>2) coaxial cable running from the radio (Lo-Z input) to the end of the
>75 foot run?

A move in this direction would foster more options when you experiment
with other antennas.

Also, use the LO-Z input, even if you don't choose to go with coax
cable right now.

>3) a north-south run?

Sure, but that isn't the answer to your immediate problem.

Hi Rees,

The advantage found in using a tuner is that it can cure "deafness"
induced by nearby strong transmitters overloading your receiver's
front end (the first stages of amplification). Such a problem is
rarely obvious aside from the general sense of lack of sensitivity -
and yet this symptom is often the most definite cue. Many who choose
to ignore this necessity proudly proclaim how good their set is, not
knowing that it could be vastly better.

Even though you may not be tuned to the local AM transmitter a couple
of miles away, its strength can be 100,000 times stronger than what
you are attempting to tune in. This signal will force its way into
your radio and develop a voltage called AGC which lowers your radio's
sensitivity - by design.

The solution here is to exclude that signal before it gets in, and to
include that signal that you want to hear so it can get in. This is
the function of a tuner. This function used to be part and parcel to
older non-computerized receivers (read tube-sets and expensive solid
state models). You can add it back in quite simply. Shop for the
cheapest amateur radio antenna tuner that has two variable capacitors,
and a switched inductor - and WITHOUT a meter. You can buy one with a

meter, but the meter will not be functional for reception, it will probably cost more, but it will still suit the required function of tuning. There are sure to be SW specific tuners out there. They don't bring anything extra to the table except for smaller size, perhaps - and they could be expensive for no real advantage.

If you read this last paragraph closely, it gives a clue to a project you and your son could engage in: constructing a tuner from parts.
Here's the simple list:
1. Box (any material, but metal is best);
2. Input connector;
3. Input capacitor with knob;
4. Switch with knob for coil inductor;
5. Coil inductor with taps for switch;
6. Output capacitor with knob;
7. Output connector.
That's it. Values for the components, how to arrange them, and where to find them can be left to investigation on the Web.

73's
Richard Clark, KB7QHC

THANKS, everyone, for the very thoughtful and thorough responses!

John KD5YI wrote:

> Check for a slide switch on the back that switches from internal to external antenna.

Would that be the ATT 0dB - 20dB switch? They show it in a figure, but don't say what it's for. I'll try it.

Sal wrote:

> Feedback to me would be nice. A Nobel Prize would be a bonus.

Your detailed suggestions of the antenna connections and troubleshooting are quite helpful. I will return to them if the new configuration doesn't work.

Jim Higgins wrote:

> Why aren't you connecting the antenna to the Lo-Z SO-239 connector instead of the Hi-Z Motorola type connector? (Other than the manual telling you to use the Hi-Z.)

Right. Apparently, Radio Shack improved the DX-394, but kept the crappy manual. Getting the antenna higher would help, I'm sure, but for now I'm stuck with what I've got.

Richard Clark KB7QHC wrote:

> If you read this last paragraph closely, it gives a clue to a project you and your son could engage in: constructing a tuner from parts.

I appreciate the suggestions. But I'm going to take the easy way for now.

These have led me to try another configuration; what I'm imagining is at http://i258.photobucket.com/albums/hh242/winwinsit/antenna2-1.jpg

The lightning arrestor I'm considering is at http://ba-electronics.com/a28.htm.

I'm wondering:

1) if this new configuration makes sense.

2) if I should use coaxial cable at A (between the tuner and the lightning arrestor) since the connectors are SO-239 and PL-259? Or should I just run more of the insulated wire?

3) about coaxial cable at B (from the arrestor to the antenna wire)?

4) if this antenna tuner would be adequate? MFJ-16010 at
http://www.universal-radio.com/catalog/preamps/1329.html. If not, any
other recommendations?

Thanks again!

Rees

Well, not sure what gauge wire it is, but I've been using cheap
speakerwire for HF dipoles with no problems whatsoever.  Not certain,
but I think this is the stuff I use here:

http://www.jaycar.com.au/productView.asp?ID=3DWB1709&form=3DCAT2&SUBCATID=
=3D992#1
```

My prime HF antenna started out as a coax-fed 40m half-wave (10m/leg) dipole made of this stuff in an inverted-V configuration. I used a home made 1:1 voltage balun at the feed point. Over time, I moved the feed point to near the back of the tuner with a short 3in length of coax, and ran a random length of 300ohm ribbon to the feed point of the dipole.

Later after reading about the G5RV, I extended each leg to 16m long. It is important to note that while similar to a G5RV, my antenna does not feature the same length of ribbon as a G5RV. The antenna is not mounted up high, the apex would be at gutter level (we have a two-storey house here). Legs tie off no higher than 2m in the air. One end ties off to a frangipannie (sp?) tree in our front yard, the other to a piece of rope running to a macadamia tree in our back yard. I have a feeling the frangipannie is helping form part of the antenna.

This antenna, while quite deaf I find on the 10m band, has worked into VK5 on 15m, I have had contacts into ZL on 20m, and it works quite well locally on 40m and 80m. I have had successful contacts using QRP power levels on 80m with this antenna, and it is very easy to tune there.

It has broken once or twice. It has never taken me any longer than about 15 minutes to repair and get back up in the air. It's also cheap enough to consider being disposable, should disaster truly strike.

So I say, go for it =85 it might as well do something useful.

Regards,
Stuart VK4MSL

Hey OM
The baluns I like to use are choke baluns and real transmission line
baluns, for ten meters and a 66% velocity factor coax that is 11ft of
RG213. That is 4:1 on ten meters only. And the high current, high
voltage nodes are at the ends of the coax.

```

I found a 50 year old pencil drawn schematic that was done by an Collins Radio engineer. So....anyone ever use a coax balun as described below?

Wind a 3.5 inch diameter with 7 turns of RG-58. Space the turns such that the coil is 4 inches long.
Connect the output of an antenna tuner to one of the balanced feedline conductors. At one end of the coax coil connect the braid to the antenna tuner output, and the center connector of the coax to ground.

The other end of the coiled coax: connect the center conductor to the other balanced feedline conductor. Connect the braid at that end of the coil to ground.

Comments?

Sounds like a pipe-dream.

It would make more sense if two coax baluns were used, symmetrically.

Many people have. It's also often referred to as a "common mode choke".

One nice characteristic of them is that they don't contain ferrite or iron cores which could saturate (and create distortion and harmonics) at high RF current levels.

>Wind a 3.5 inch diameter with 7 turns of RG-58. Space the turns such that
>the coil is 4 inches long.

I'm not sure why he specified hooking the braid to the tuner output and the center conductor to ground. Most people do it the other way around (it's easier to connect to a PL-259 that way).

Doing it his way brings the "hot" side of the tuner output out closer to where one might touch it... there may be more of a risk of a shock or flashover-to-ground situation here, if the SWR on the line is high and the tuner is looking into a high impedance at the input of the choke.

This may not be an issue in your particular deployment.

>The other end of the coiled coax: connect the center conductor to the other balanced feedline conductor. Connect the braid at that end of the coil to ground.
>
>Comments?

http://www.hamuniverse.com/balun.html shows numerous variations on this same basic idea, and there are about a zillion others out there on the Net and in the literature.

There are numerous variations:

- Single-layer solenoid-wound (as in the one you described), either close-wound or spaced.

- Multiple-layer solenoid-wound.

- Scramble-wound.

Different winding style will give different amounts of inductance, and different (sometimes very different) amounts of distributed capacitance.

If I understand the situation correctly, a winding style with low distributed capacitance (e.g. single-layer solenoid-wound with space turns) functions primarily as a common-mode inductive choke... fairly broad-band, *if* you have enough turns to give you the necessary amount of common-mode inductance.

A choke which is multi-layer (perhaps even scramble-wound) can have more distributed capacitance, and it can act as a parallel-resonant trap at certain frequencies... giving a nice, high choking impedance at those frequencies. Above and below that resonance, though, its impedance can drop off fairly rapidly, and it may not choke the line effectively. Coaxial chokes of this sort are (I believe) often wound to give optimal performance on one or two bands.

[I could well be wrong about these details... it's been a while since I looked at this subject in any detail.]

Wayne, the device as you describe it is a form of balun (being a device that facilitates a transition between states of balance).

Considering the ATU output terminal to have voltage V, V is applied directly to one feedline conductor, and if the common mode impedance of the coaxial choke is sufficiently high and its length sufficiently short, approximately -V to the other conductor... so it implements a 1:4 impedance transformation.

The problem is with the "sufficiently" qualifications above. The common mode impedance of a coil of coax like this has been well explored, it has a very high impedance over a narrow range near resonance, and mediocre to low away from resonance, and so not well suited to broadband use.

Nevertheless, these types of things have appeal to those who are prejudiced against ferrite, or who just do things on the cheap.

I hasten to add that I have used just such a coil of coax as a single band 1:1 current balun, but it was carefully resonated for the band in use, and it measured much higher common mode impedance than practical ferrite cored baluns.

Mentioning current baluns, you describe a balun that could not be categorised as an effective current balun, as if you were to ground the side of the load direct connected to the ATU, the whole thing fails.

I know that to many there is a magic to all things that came from Collins, but you don't see this widely done, and for good reason.

Owen

I have had success using a construction similiar to:

http://www.arising.com.au/people/Holland/Ralph/CM4Balun.htm

Two coils are made out of two pieces 75 Ohm coax, each 4m long.
As coil forms i'm using tubular foam pipe isolation. I dont know
the correct word for them in English ;) The type used has a diameter
of 6 cm.

These baluns has served me well. Using TV-coax, the whole construction
wheights very little.

I know that to many there is a magic to all things that came from Collins, but you don't see this widely done, and for good reason.

Owen
****
Thanks for the comments Owen. I was curious about the schematic, but tend to stick with my "on hand" ferrite baluns.

FDC FD-880 Dual Band 136-174/400-480Mhz FM Radio

http://www.409shop.com/409shop_product.php?id=3D106081

Special features

Dual band,dual Freq.,dual display and dual standby
Working Mode:U-V,U-U,V-V can be set freely.
Band can be set freely on the same channel:VHF TX-UHF RX or UHF TX-VHF RX.

PTT ID function;DTMF function
Offset Freq and Freq.shift direction can be set.
Keypad lock (Auto/Manual);Busy channel lockout

Water-proof;Wired clone function
Built-in FM radio;Led flashlight
3 displaying modes selectable(CH,FREQ,CH Name)

VOX function;Stopwatch function
Priority Scan;Multiple Scan modes;Adding channel scan
Emergency Alarm function;Wired clone function

Reverse freq.function
Multipe Step frequency(5/6.25/10/12.5/25/50/100KHz)
Charging directly from the power supply.You can also charge your radio by connecting the supplied ac adapter directly to your radio.

Technical specifications

Model NO. FD-880(Dual-band)

General Frequency Band	VHF UHF
Frequency Range	136-174MHz 400-480MHz
Channel Capacity	128
Operating Voltage	7.2V DC =B115%
Antenna Impedance	50O
Channel Spacing	12.5kHz/25kHz
Working Temperature	-30 ? - +60 ?
Frequency Stability	=B12.5 ppm
Size (Without Antenna)	104(W)mmx62(L)mmx36mm(D)
Weight(With Battery)	about 250g
Battery	1500 mAh(Li-ion)
Transmitter RF Pwr Output	5W/4W
Modulation Type	F3E
Modulation Distortion	< 5%(300-3000Hz)
Max Freq Deviation	< 5kHz(1000Hz When 100%)
FM Noise	<=3D-45dB

Receiver

```
Sensitivity                 (12Db SINAD) 0.16=B5V
Selectivity                 55dB
Adjacent Channel Selecivity  >=3D70dB
Noise Respond               >=3D60dB
Communication Range         3-5km(Downtown),6-20km(In the Open Area)
FM Noise                    30dB/40dB
Modulation Type            8K/16KF3E
Audio Power Output          500mW When Distortion Less Than 10%
Audio Distortion            < 5%
Operating Bandwidth         =B13.5kHz/3.75kHz
Standby Current             < 12mA

Each Set PACKAGE CONTAIN

1 x FDC FD-880 (VHF136-174 / UHF 400-480Mhz Dual Band)
1 x 7.4v 1600mAh Li-ion Battery
1 x Dual band Antenna.
1 x Belt Clip.
1 x ENG Manual
1 x Wall Charger PSU  (Provide PSU plug for your Country)
1 x 12V Car Charger Cable
1 x PTT Earpiece for free

I'm sharing a good experience I had with LDG. At our local club meeting, Thursday, Aug 4, I bought an LDG AT-11MP. It's a discontinued item. At $10.00 it was a bargain but it needed two new front-panel toggle switches. They were physically damaged.

On Friday, Aug 5, I messaged LDG on their website and asked how to buy them switches. I said I'd send a check if they shipped with an invoice. The next day, while browsing in a surplus store, I found switches and put them in, so I messaged again, saying I had repaired the unit. I said if they had already sent me two switches, I'd honor the invoice and keep the switches.

Imagine my surprise when I got an email a few hours later (still Saturday) saying thar the switches were scheduled to go out but may not have been shipped. If I receceived them, I could just keep them! So apparently they weren't even going to invoice for them! A gift!

Life is Darn Good (get it?) and they made a new friend.

Having but recently returned to the world of shortwave radio, I'm trying to be better informed about technical and safety issues than I was as a kid. Now a homeowner with a mortgage and a homeowner's insurance policy, I'm worried about lightning protection. I'm receiving only, not transmitting. I have a ground rod just outside the window where the antenna wire enters, and I intend to disconnect the antenna outside the house when I'm not using the shortwave. But I want to be extra careful!

So I'm considering some options. Which make sense to you seasoned hams? Do any of these leave me open to my homeowner's insurance being voided if I get a direct hit by lightning?

I ordered this before I read the disclaimer: just "better than nuthin?"

http://www.universal-radio.com/catalog/protect/4618.html

The Opek A7516 Lightning Arrestor is not the "state-of-the-art" in radio protection. These "air gap" arrestors were OK for tube sets, but are not the best for today's solid-state rigs. However, if you are on a budget, this device is a whole lot better than nuthin! As with all lightning protection devices; you must connect it to an earth ground with thick ground wire, and it is not going to provide protection in the event of a direct hit.

So, here's a better gas-discharge arrestor:

http://www.universal-radio.com/catalog/protect/5611.html

The LDG SP-200 surge protector operates from DC to 1500 MHz with a 200 watt power capacity. The SP-200 protects coax feedlines from surges exceeding 230V, such as caused by nearby lightning strikes and static build-up. The SP-200 employs a gas-discharge tube that arcs-over when 230VDC is exceeded between the RF center pin and shield connections.

A variation, with different connectors:

http://www.radiolabs.com/products/antennas/accessories/lightning-protection.php

Ultra Fast Gas Discharge
0.4db Max Insertion Loss
350V or 90V Breakdown Voltage
VSWR Better than 1.5:1
Passes DC voltage
200W Operation

This doesn't say if it uses gas or air:

http://www.jetstream-usa.com/instructions/jtla1.pdf

Model # JTLA1
1.5-200 Mhz
50 ohm
8 kW PEP, 4 kW DC
Insertion Loss: Less than .1db
Surge Current Capacity 20,000 Amperers
VSWR Less Than 1.1:1 @ 1000Mhz
Voltage Attack Time: 0 to 10 Billionths of a second

```
Can I use something like this?  It's designed for fences, but could
easily be rigged for an antenna input:

http://www.zarebasystems.com/store/electric-fence-accessories/la1

Protecting the fence charger from lightning strikes on the fence line.
This lightning arrestor creates a path of least resistance, diverting
lightning surges to the ground.
-----------------------------

What's going on here?

http://ku5e.com/index-59869.html

The lower picture shows a device mounted atop the ground pole.  Do you
recognize it?

Hi Rees,

For the Home:

If you implement an intention to control lightning hazard, I would suspect a jury would see it your way if you sued the insurance company for failing to uphold their policy with you. However, they might grieve at yielding to the insurance's arguments against you.

It wouldn't get to trial if you could demonstrate that you met the electrical code.

The elephant in the room is: have you properly installed that ground rod? Driving a long one deep into the ground does not qualify for a "yes" to that question.

Ground is a very complex and mysterious thing for many, many people. The electrical code doesn't go any great distance to inform you of its mysteries, but it does give you solutions that work.

For the Receiver:

As for protecting your receiver from the lightning risk presented by putting wire up into the air. All of the lighting protectors you have links to guarantee you will see a couple of hundred volts across the terminals. The receiver is not going to survive. The distinction between near strike and direct strike are not really material to the problem of frying the receiver. The difference is merely one of personal drama.

You may encounter this potential even on a seemingly cloudless day.

Receiver solutions:

Short the potential. This may be accomplish by using the "Folded Dipole" design of horizontal antenna. A "Folded Monopole" design for a vertical antenna. Other designs that employ loop coupling would also reduce the risk. All such options offer a DC short, but with an RF impedance. This insures static electricity drain, but allows an RF voltage (the short wave signal) to develop. A large inductor across the feedline or conventional dipole feed point provides the same protection. The coil acts as a DC short, but as an RF open.

Some SWL lightning protectors employ paired diodes to reduce the voltage risk to less than 10V - trivial indeed. Unfortunately, these same diodes will conduct in the presence of large RF fields (recall my discussion about nearby AM transmitters, and "nearby" is relatively near for RF but seemingly distant if you had to walk or even drive to it). This conduction will ruin listening opportunities with a jungle of mysterious signals "that shouldn't be there." Example, hearing an FM rock station feed on the 60M band.

Having a Tuner between your radio and antenna shifts the dynamics such that the gap arrestors are useful - until you throw the bypass switch.

Could you state this a different way, as I don't follow the grounded
output reference.

I have written some notes about baluns in antenna systems at
http://www.vk1od.net/balun/concept/cm/index.htm . The notes explain why
a current balun is most suited to 'general purpose' antenna application.

In an ideal current balun, the current in each output wire should be
independent of whether one terminal or the other is grounded.

In the case of the balun describe, grounding one or other output
terminal has a large effect on output current in each of the wires.

Proponents of some balun designs insist that they work perfectly into an
isolated load. Of course, it the load is truly isolated, ie there is not
current path to ground from the load, then they are correct, but you
don't need a balun in that case because since the load is properly
represented by a two terminal network, the current into one terminal
MUST equal the current out of the other terminal. Problem is that real
antennas aren't necessarily will represented by a two terminal network
(though we often talk as if they are).

Owen

Nice people, nice company, and great service. However, the justification may not be so altruistic. For small parts, the cost of the parts may be insignificant compared to the handling. That especially applies to returns. It would cost LDG far more than the cost of the switches and postage to inspect the customer returned parts, return them to stock, and deal with the paperwork. With electrical parts, it's assumed that anything that has been in the hands of the customer, has a good chance of being fried. Try returning electrical parts to a hardware store or automotive supply house, and watch the fun.

I had something similar happen with Digikey a few years ago. They shipped me some parts, but the USPS(?) delivered the parts to the wrong mailbox. After about 2 weeks, I was getting desperate and called Digikey, asking for a duplicate shipment, which I indicated I would pay for, and return the original package should it ever magically appear. Digikey sent me the replacement parts at no cost. Two weeks later, the original package appeared. I called Digikey asking how to pay for the parts, or for return instructions. They indicated that it was cheaper for them to just forget about the parts and the added charges or to deal with the returns. So, I accidentally received $70 in spare parts from Digikey for free. I like Digikey.

While I'm ranting on the subject, at a former employer, I once calculated that the cost of shipping an empty box was $75. That's a product with zero cost, but which still needs all the paperwork, inspection, packaging, handling, billing, and overhead of any other product. That means to ship a single transistor, the minimum the company should have charged was $75. As a result of my calculations, it became common for the company to provide massive quantity discounts simply to reduce the number of orders by a given dealer. Pricing such as:

1 xsistor	$30
10 xsistors	$35
100 xsistors	$40

was common. There was also a trend to sell production extras by the hand full or by the paper bag full as it was cheaper to do this than to sort, separate, test, and re-file the random parts. Since all of them were used in various radios sold and repaired by the dealers, everything in the grab bag was probably useful.

A dipole doesn't have to be without bends. Keep those bends fairly
less than 90 degrees at any one point and it should work okay. It
also doesn't have to be suspended exactly at the center feed point,
for instance, if the support isn't exactly 'centered' in your lot.
Lot's of possibilities. May not be the best in the world, or a
'classic' shape, but with a little 'fudging' here and there can
usually be made to 'fit' your available space.
 - 'Doc

(Since that saying isn't literal, but a 'play on words', I doubt if
politics have much to do with the capitalizing. But then it could, if
you're of such a bent.)

Sorry, but that would be prior art:
<http://cybraphon.com/process/the-emotion-meter/>
<http://www.flickr.com/photos/cybraphon/3789780162/in/pool-917701@N24/>
<http://en.wikipedia.org/wiki/E-meter>
I worked on something similar for the audiophile industry, when I
invented an ambience and presence meter.

Personally, methinks the correct solution for such technical problems
is to virtualize everything and eliminate the antenna and radio:
<http://www.hamsphere.com>
<http://qsonet.com/programs.html>
With these, you can have all the frustration of DX, without the
expensive equipment and temperamental ionosphere.

Do try to have a better day (as measured on the emotion meter).

I tend to agree Mark, I don't have a lot of experience on 80M, but have been a Ham for 50 years. Propagation, the thing I know least about, is the logical answer. I will encourage him to keep trying the modified antenna at various times of day to get some better data. Hopefully, it will prove the better antenna, and the newbie will learn something in the process.

I was a Navy tech at a base in the Philippines in the early 1960s. Late one night (we were a 24-hour operation) with nothing much happening, one of the operators was in my shop, goofing with an ohmmeter. He picked it up and squeezed the leads, deflecting the needle some.

I don't know what possessed me but I told him to press the leads to his temples. It deflected a bit more. I explained that he had less resistance

in his head than in his whole body, and declared him "smart" for that
reason. Well, he got the joke immediately and we laughed about it.
However, it didn't stop him from parading a goodly number of the watch
section into my shop for Intelligence Testing. Oh, my!

It never occurred to me that he would put his underware on the loading coils. I thought he would use some wire and jumper them. Mystery solved.

The whole idea was to get the Kid on the air, and excited about Ham
Radio, by making his first HF QSO with his Dad.

I think the learning will come later-he is a Patent Attorney-EE and
Law degree. He impressed me Field Day when we were on an Island on a
lake in South Carolina on 900 watt generator power. Had a lot of
Impulse noise on RX even tho we were miles from power lines. Decided
it was from the SMPS powering the Computer we were using for logging.

The batteries on the Computer were good for ~1 hour, so we could not
disconnect the SMPS for long.

While we were fretting over what to do, he butchered up a spent beer
can, and enclosed the SMPS, dropped the noise considerably, I was
impressed.

I hope he enjoys Ham Radio, in spite of my questionable advice.

Think of the experience in a different way. If ham radio propagation were predictable and consistent, it would not be any fun. Just pickup the microphone, set the controls, and talk to anyone in the world. Kinda like a cell phone. It's the vaguarities of propagation, the magic of sub-optimal antennas, and the mysteries of operation that make ham radio fun. Considerable expense and effort, on the part of major players and governments, to obtain reliable HF communications has not been very successful over the years. Possibly "reliable HF" is an oxymoron. Welcome the "kid" to the magic part of ham radio and suggest that he adjust his expectations accordingly.

Incidentally, I usually carry a folded wad of aluminum foil for improptu RFI/EMI shielding, probably because I don't drink beer.

Good comments Jeff, I will keep them in mind next time I talk to him.

Too bad you don't drink beer, the "Learn by destroying" gets really
easy after a couple. Or maybe it is just the destroying that gets
easier.

FDC FD-880 Dual Band 136-174/400-480Mhz FM Radio
http://www.409shop.com/409shop_product.php?id=3D106081
Special features

Dual band,dual Freq.,dual display and dual standby
Working Mode:U-V,U-U,V-V can be set freely.
Band can be set freely on the same channel:VHF TX-UHF RX or UHF TX-VHF RX.

PTT ID function;DTMF function
Offset Freq and Freq.shift direction can be set.
Keypad lock (Auto/Manual);Busy channel lockout

Water-proof;Wired clone function
Built-in FM radio;Led flashlight
3 displaying modes selectable(CH,FREQ,CH Name)

VOX function;Stopwatch function
Priority Scan;Multiple Scan modes;Adding channel scan
Emergency Alarm function;Wired clone function

Reverse freq.function
Multipe Step frequency(5/6.25/10/12.5/25/50/100KHz)
Charging directly from the power supply.You can also charge your radio by connecting the supplied ac adapter directly to your radio.

Technical specifications

Model NO. FD-880(Dual-band)

General Frequency Band	VHF UHF
Frequency Range	136-174MHz 400-480MHz
Channel Capacity	128
Operating Voltage	7.2V DC =B115%
Antenna Impedance	50O
Channel Spacing	12.5kHz/25kHz
Working Temperature	-30 ? - +60 ?
Frequency Stability	=B12.5 ppm
Size (Without Antenna)	104(W)mmx62(L)mmx36mm(D)
Weight(With Battery)	about 250g
Battery	1500 mAh(Li-ion)
Transmitter RF Pwr Output	5W/4W
Modulation Type	F3E
Modulation Distortion	< 5%(300-3000Hz)
Max Freq Deviation	< 5kHz(1000Hz When 100%)
FM Noise	<=3D-45dB

```
Receiver
Sensitivity               (12Db SINAD) 0.16=B5V
Selectivity               55dB
Adjacent Channel Selecivity  >=3D70dB
Noise Respond             >=3D60dB
Communication Range       3-5km(Downtown),6-20km(In the Open Area)
FM Noise                  30dB/40dB
Modulation Type           8K/16KF3E
Audio Power Output        500mW When Distortion Less Than 10%
Audio Distortion          < 5%
Operating Bandwidth       =B13.5kHz/3.75kHz
Standby Current           < 12mA

Each Set PACKAGE CONTAIN

1 x FDC FD-880 (VHF136-174 / UHF 400-480Mhz Dual Band)
1 x 7.4v 1600mAh Li-ion Battery
1 x Dual band Antenna.
1 x Belt Clip.
1 x ENG Manual
1 x Wall Charger PSU  (Provide PSU plug for your Country)
1 x 12V Car Charger Cable
1 x PTT Earpiece for free

Just in case anyone is also struggling with this problem I thought I would share how I worked it out. I have two AB-952 antenna masts. These are the thirty five foot masts that were used with a multiplexed tube radio system that provided the wonderful capacity of twenty two voice channels between major element headquarters of the Army in Korea. I have obtained an extension kit that extend the height to fifty foot. I was trying to assemble a second extension kit from parts because I couldn't find another complete extension kit.

Now to the problem. It is difficult to adapt antennas to the four inch tubes that make up the mast assembly. It is hard to find boom clamps that large. I found a source for the adapters that were used to support a different antenna than the one for which the mast was originally designed. Instead of the offset adapter that was used to support the corner reflector antenna this masts was originally designed for, I found the adapter for the dish antenna that was added to the system later. The dish adapter comes straight up out of the top of the mast and reduces in size to 2&1/4 inches outside diameter to accommodate the clamps that were on the dish reflector. That is well within the range of most of the boom to mast clamps that Hams use. I had seen these adapters only in manuals but I was picking up an extension kit, that Ben at Ontario Surplus helped me locate, from another surplus dealer and recognized the adapters that he had in stock. The dealers name is Tim Clark. He's in Lyndon, MD. He can be reached via [glengar comat verizon period net]. For those who do not recognize the term comat it is the "commercial and" that we all call at. If your into military stuff he has quite a lot of other GI stuff as well. My only relationship with Tim is that he has now supplied me with the parts to complete my AB-952 Mast assemblies at a very manageable cost after I was on the verge of giving up on ever completing them.

It took five years of patient searching but now both masts are complete. They allow me to hoist any of the smaller beams to fifty feet off the ground and to use the newly found adapters to attach a rotor or to directly attach a boom clamp and aim by turning the mast assembly from the ground using the strap wrench which is part of the basic mast accessory kit. These masts are really quite useful for any kind of field deployment such as field day, Boy Scout Jamboree on the air, public service events, and the list goes on.

I just thought that someone else might be working with these mast assemblies and could use help finding a good source of parts.

Well, the slogan is not quite what it seems. I was graduation from Cal Poly Pomona back in the days when the skool slogan was "Learn By Doing". The basic education plan was to get as much hands on experience for the undergrads as possible. We modified the slogan to "Learn by Destroying" which had more than a little truth to it. I discovered quickly that the easiest way to understand how something works is to (accidentally) break it, and then desperately attempt to fix it before I'm discovered. It's a great way to learn, but does tend to get rather expensive. A less drastic version is sometimes called "sensitivity analysis" where one uses or installs a device in some manner in which it was never intended to function in an attempt to see how sensitive it is to installation and operation creativity. This works well with antennas, where there are almost an infinite number of ways to do it and still have it function.

We have some local hams that have never removed the screws from their radios and looked inside. I often do this for them, while they complain about warranty and loss of resale value. Tearing the radio apart and giving them a tour of the guts (sometimes at radio club meetings) is also fun (to watch them sweat).

You now have the unenviable task of acting as mentor to this new ham, who apparently has the potential for more than minimal understanding and knowledge. You may soon find yourself doing some furious reading (or Googling) in order to just keep up with him. I've done this a few times, where my usefulness eventually ends when the new ham tells me I don't know anything. I just smile, and await the next victim.

I'm getting back into radio after a 20 year absence. Back then, I had a QRP rig and a novice license; didn't worry too much about my antenna unless the SWR meter went past 2.5. What I did not have was an antenna tuner.

Now that I'm older and wiser, I realize an antenna tuner is probably a necessary thing to have. I'm putting up an 18' Hy-gain 5 band vertical antenna, leading to a Yaesu FT840 @ 100 watts. The matching ATT is not available, unless I'm willing to bid on E-bay for a hundred more than it cost new. (Believe me, I've tried this.) But I don't know what I should use. I know some tuners are designed for a specific rig.

Does anyone know what I should get? I'd really just like to turn on the radio, move to a frequency, turn on the ATT, and tap away. Help!

Anyone have experience making a dipole from 18 gauge speaker wire? I
have a whole lot of it lying around the house, and was wondering if I
could put it to some good use.

Firstly, is an ATU really necessary with your antenna. One of the selling points of these kind of antennas is that they are a fair match to 50 ohm line... though an ATU might overcome to some extent the narrow bandwidth on the lowest bands.

Next, there are a range of generic automatic ATUs, they fall broadly into those intended to go into a coaxial line and those intended to feed unbalanced loads like end fed wires, monopoles etc. The each have different matching ranges and applications.

Some of these generic auto ATUs can be interfaced to proprietary ATU interfaces on transceivers. Some transceiver support for ATUs is quite poor and might be construed as a marketing ploy, eg most Icom transceivers seem to abort a tune process after about 18s, so they do not integrate well with an ATU that might take 30s to find a match.

This lack of open interface, and flexible support is a problem. I attempted to design a protocol converter to properly integrate an SGC237 with an Icom radio, but I abandoned it because the SGC cannot be guaranteed to complete within 18s, and if it has to restart, it restarts from scratch and the same problem occurs. On the other hand, I was able to make a reliable protocol converter for a 'screwdriver' type ATU, as in the rare circumstance that the tune had not completed when the Icom aborted, the coil contact was closer to the desired point and in tests, always completed on the next attempt.

So, in my experience, Icoms work reliably with Icom ATUs, but have issues with some non-proprietary ATUs. This is why I say that ATU support is used as a marketing ploy.

If it is copper wire, it is more suitable than many things proposed for antenna conductor, though annealed copper is relatively low strength material.

Opinions vary, but wire insulation contributes little, if any, strength, but substantially increases wind resistance and mass, so it compromises the ability to withstand high winds.

The next question often asked in your situation is whether the speaker wire makes a good feedline. Contrary to popular belief, PVC insulated figure-8 cable is not a good feedline for HF antennas.

Owen

PS: hams universally ignore the guidance of NFPA 70 which makes recommendation on conductors for antennas.

I have an internal autotuner but one ham buddy uses an LDG auto tuner for 100 watts and he's happy with it. (He uses a high-power manual tuner if he's using his amp.)   http://www.ldgelectronics.com/

Some models, LDG or other, may be more suited to the FT-810; some radios have a <TUNE> button that talks to the tuner via a custom cable, while putting out Tune Power, about 10 watts. Otherwise, there should be no great difficulty in you dialling up a tune power output and invoking the <TUNE> finction on the tuner.

Good luck, OM

Maybe because NFPA 70 costs $150 US?

Yes, standards are expensive things and it is a frustration when researching.

Anyway, NFPA makes recommendation on the wires for ham antennas specifically, and it may be binding in some places.

I suspect the reason for ignoring it is that the advice is unaccepable to most hams.

That said, it does seem over the top in some areas, and is hardly comprehensive in its thinking. For example, the prescription for feedlines seems to not be aware of the existence and use of coax.

I guess it is these gaps that give critics the basis for arguing against the whole thing.

Anyway, in respect of antenna wires, it does not 'permit' anneallead copper or other low strength materials, and it 'requires' a minimum conductor diameter of #14 for up to 150' span.

They may have had in mind the risk to persons and property where low strength conductor are broken in high wind and make contact with power lines.

Should work fine with the caveats of added weight from the insulation, etc.

Some years ago, there was a QST article written by a ham who built a 20
meter quad using insulated wire.  He found that it changed the expected
resonance, IIRC downward.  So you may have to play with the length a little
more than expected from the calculated lengths.

Recently acquired a 50W 2 meter rig, and I'm wondering if using aJ-pole
made of 300-ohm twin lead as an emegency antenna would be feasable..or
would the rig be tuned for maximum smoke?

This topic is likely to spur a lot of discussion. For a while two of us
were using zip cord
which in itself is frequently used as speaker wire.

Mine was strung across and somewhat around the back yard to I could work 75m
and up with a tuner.

George, VE6VA surprised me when I noticed he had a feedling going out of his shack -- it was cloth covered line cord! Both of us had lots of fun on the bands.
I should add that my transmission line and both halves of the dipole were made
from one piece of line cord/speaker wire -- I just brought the end of the transmission
line into a plastic wire-tie, and fed the lines around the yard, using a couple
tree branches and a small pole on the garage. The other dipole half was just
long enough to reach the front of the house where it was then suspended
by a small lilac bush and a tall fir tree. End insulators were just bits of
scrap plastic and both ends were suspended with a long string of short
and medium pieces tied together! From experience I think that I can
generalize that you matter how much nylon line a ham buys, in time
it degenerates into a wide assortment of randomly short lengths, none
of which alone can serve any purpose!

After 50 plus years of hamming fun, I have come to the conclusion that
anything with a little metal in it will serve as an antenna if you hook it
up in the right manner. It has truly surprised me over the years just
how little antenna I had, and how far it was getting out.

Some antenna's will work better than others, and eventually every
ham, whose expectations eventually approch infinity will want to try
a 'better antenna'. Aside from collecting materials, and it doesn't
take much to make a dipole, once you know where you can string
your wires, it's easy to try a variety of antennas. In the long run
you will probably find that a half wave dipole will do the best,
and if you can drop the ends, changing it into an inverted-Vee
you will have near omnidirectional operation on the higher bands.

Antennas, discussed here have impedance, Jx+something or other, specific lengths,
and so many rules that your life as a ham will make you miserable
when you dare approach the shack. Throw an arrow into the
air (throw an antenna into the air), suspend it here and there, and
then see if it works. If it does, Great! -- If it doesn't -- well, try
something else. Chances are you will have so much fun that
you postpone tidying up the knots, but some of those things
stay up for ever until their age approaches that of a typical
old fogie antenna fussy, Smith chart interpreter, know-it-
all hams, like most of us here

Antennas are funny people!

Get the wire up, have a ball!

Irv
VE6BP, Calgary

Political correctness is a doctrine, fostered by a delusional, illogical minority, and rapidly promoted by an unscrupulous mainstream media, which holds forth the proposition that it is entirely possible to pick up a piece of poop by the clean end.

Search at google.com for twin lead j pole; twinlead jpole; jpole twinlead;
j pole twin-lead or some such combination. I found approximately 137,000
search returns whichever way I tried it. You didn't.

Afterward, search for the correct version of your insult against France.
It's misquoted.

My favored gauges are 12 and 14. I took a dipole I modeled in EZNEC
(Evaluation Version) and changed from 12 gauge to 18 gauge. The behavior of
the antenna changed dramatically.

No, I'm kidding. EZNEC showed insignificant shifts in VSWR and gain at
optimum takeoff angle. You apparently face only mechanical issues. If the
wire parts when you pull it up, you'll need to connect it to a stout span
line.

I have two 20m dipoles hanging, one with a span line and one free-hanging.
They were both temporary ... last year.

Yes, I freely admit that I was a sucker who implemented that type of
antenna system on the advice of mentors.

Since learning those j thingies that you deride, I have come to learn
enough to quantify the sacrifice in performance.

Yes, it 'works', whatever that means!

One way to make sure newbies never challenge you is to lead them down
the same misdirected paths as yourself in the hope that they never catch

up.

Whilst there are those who glibly recite that "any antenna is better than no antenna at all", it is also true that you might work stations on any antenna, just you will work more on a better antenna.

I know that dumbing down the hobby is the fashionable trend, deride those who see ham radio as an essentially techical exploit as the new age ham is embarking on a social experience, just the connectivity is several orders of magnitude below those of most social network appliances. Whilst cutting edge hams are breaking DX records with things like WSPR at <0.5bps, kids are socialising on mobile phones at greater than 10Mbps.

When you take the passion for understanding the technology out of ham radio, it just doesn't compete.

Owen

Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

Sal, there would be those who would chide you that such an antenna
obviously wasn't big enough... in the sense that "if it didn't blow down
last season, it wasn't big enough".

And we wonder why so many housing block have restictive covenants that are
not ham friendly. We might just have bought that on ourselves to some
extent.

Owen

On Sun, 31 Jul 2011 13:30:17 -0700, ehoops rearranged some electrons to say:

> I'm getting back into radio after a 20 year absence. Back then, I had a QRP rig and a novice license; didn't worry too much about my antenna unless the SWR meter went past 2.5. What I did not have was an antenna tuner.
>
> Now that I'm older and wiser, I realize an antenna tuner is probably a necessary thing to have. I'm putting up an 18' Hy-gain 5 band vertical antenna, leading to a Yaesu FT840 @ 100 watts. The matching ATT is not available, unless I'm willing to bid on E-bay for a hundred more than it cost new. (Believe me, I've tried this.) But I don't know what I should use. I know some tuners are designed for a specific rig.
>
> Does anyone know what I should get? I'd really just like to turn on the radio, move to a frequency, turn on the ATT, and tap away. Help!

I agree with Sal, LDG makes a good product. I have a Z11Pro2. It doesn't require any interface with the radio, it measures the incoming RF and antenna side SWR to know when to tune. It also latches the settings, so it stays set up even if I take power off of it (which I do when I'm not trying to tune it).

Hello, I'm about to fix a 20 foot aluminium pole to a couple T+K standoff brackets about 1.5meters apart and standoff about 16 inchs I'm wondering what size of Rawbolts to use ?? I'm think 12mm ??? Oh yes on the pole would be a 2/70cm co-liner and a 66ft longwire on a pulley no great size or weight

Any advise links would be good !

Thanks

To answer your question Pad,
Yes, 300 ohm feed line will do quite well for 2 meters at 50 watts IF it's
made correctly and you have a good match.

Kevin, WB5RUE

Quoted correctly or not it's still accurate.

They say it can be done... Not my choice though. I prefer simple 1/4
wave ground planes as simple emergency or temporary antennas.
IE: a 1/4 wave ground plane can be made with five pieces of wire
and an SO-239 connector. Or a telescoping whip that can extend that
far, and four pieces of stiff wire for radials, which would be bent
out at about 45 degrees.
I think the 1/4 wave ground plane will be a better decoupled antenna
vs the usual J-pole, assuming no other decoupling methods are applied.
Another advantage is no matching schemes are required.

Free at the library, and at various sites for California Title 24.
http://rrdocs.nfpa.org/rrserver/browser?title=/NFPACA/CaliforniaElectricalCode2010

And the sections on antennas are widely quoted. I don't think cost of a copy of the code is why hams don't follow it.

here you go:
II Receiving Equipment - Antenna Systems
Article 810.16 Size of Wire-Strung Antenna -Receiving Station
(A) Size of Antenna Conductors. Outdoor antenna conductors for receiving stations shall be of a size not less than given in Table 810.16(A)
Table 810.16(A) Size of Receiving Station Outdoor Antenna Conductors
Minimum size of Conductors (AWG) where Maximum Open Span Length is:

	Less than 11m	11m to 45m	Over 45m
Al Alloy, hard drawn copper	19	14	12
Cu Clad Steel, Bronze, other high strength matl	20	17	14

Or
III Amateur Transmitting and Receiving Stations - Antenna Systems

	less than 45 m	over 45 m
Hard drawn copper	AWG 14	AWG 10

CCS, bronze, etc.   AWG 14   AWG 12

Are you saying the electrical code is sort of like the pirate code? more guidelines than actual requirements?

I think the way that hams can rationalize it is that most wire antennas (particularly those made with fine wire) are, by their nature, "temporary installations". The finer the wire, the more temporary.

You have a point Mark.  I agree that a simple 1/4 wave groundplane is more
study and very easy to make using an so-239 and some piano wire.  Steel wire
can be soldered right into the back, four bolts with nuts and four more
peaces of wire around 19" long with a bit of a downward bend and you have a
very good antenna.

At least it's good to see that my posts are making it out!  ;)

The French, in the cities tend to be rude and arrogant -- kind of like New
York City but worse.  In the smaller towns they are quite pleasant and
welcome tourists as long as they don't act like "rude Americans" and expect
"special treatment."

I think that 12mm will be just fine. I'm in the US and some of your terminology is a bit obscure to me, in particular "rawbolts" and "T+K standoff". But I'm bilingual, I speak inches and meters so bolts of that size should hold that short of mast up just fine if the standoffs are up to the task.

It won't smoke if the antenna is tuned, but you could get burned from
the rig or mic.

Those antennas need to have serious choking done on the feedline, at
least 2 a quarter wave apart on the feed just before the antenna.

Doing so helps make the pattern more like what is expected and reduces
hot radio and mic issues.

```

Examples 7 and 8 in the catenary calculator at
http://vk1od.net/calc/awcc/awcc.htm use #14 and #10 HDC. Readers can
explore the survivability of wind and ice with the calculator.

If I model a 45m simple span of #14 HDC at the lowest wind speeds
applicable to the design of structures in this jurisdiction, using the
mandated safety factor, the minimum sag is about 5% of span, about as
large as it typically practical for such a span.

NFPA 70 does not apply in VK, though there are standards that apply and
the answer comes up pretty much the same, just there is more freedom in
engineering shorter spans.

Thanks John, You've already guessed I think that I'm in the UK where we seem to mix up units of everything quite happily millimetres', inch's, pints, litres, Km, miles

Anyway back on topic the T+K bracketts are just the shape T at the top and K shape at the bottom. One thing I forgot to add was the wall type it's a 'breeze block' construction or cemet block I think that's a cinder block in the US, and the wall has a filled cavity.

Stainless steel mig welding wire.
Any reason why this won't work as a wire antenna?
Very strong, fairly cheap, but doesn't like kinks.

It is small diameter, high resistivity material. If it is magnetic, even worse.

I depends on its length, and the current flowing.

The article http://vk1od.net/antenna/conductors/loss.htm includes an example of 316 SS MIG wire.

It is great for stealth antennas, actually doubly so, because not only is it hard to see, it is hard to hear.

Owen

I don't have any CCR problems but I do have a vertical antenna of
about 28 feet cobbled together and the SGC-237 does a great job with
it. The SGC-237 is pricey but I don't think it can be beat.

Several years ago I used 4 fifty foot extention cords on top of the
ground for radials and it did work. I experiment with antennas a lot,
so everything at my qth is always changing.

Perhaps you can glean a little inspiration from
http://dixienc.us/28FtVert/28FtVertical.htm

There are some nice light weight fiberglass whips on the market in the
$100 range. One of these days I will follow that path.

I'm actually checking with the HOA about this. Would be a perfect
solution in my case. Any suggestions about which works best?

Thanks!

> The antenna would be about 4 feet away from the house. The house is 20 ft high at the peak of the roof (single story). The roof is concrete tile. I've looked into suspending a wire from a telescopic pole but it seems like it would be a little cumbersome to raise and lower. I've looked at suspending a long wire between front and back yard trees but that is a little more permanent and the HOA could bust me if they saw it. This is why I'm thinking a vertical would be less visible, easier to setup and take down, and has a fairly small wind load. I do favor 20 - 10 meter bands so that might be a prob elm for the design I'm considering. I love the fact that cheap, small diameter pipe can work as well as a commercial product. Thanks for that info!

If 20 meters and up is your primary interest, instead of a base fed vertical make it a vertical dipole with the length based on 20 M.

This has the advantage of not having to have a RF ground.

The depth is deep enough to cover them with dirt.

Since they are buried, the absolute length isn't particularly important, just
put in as many as you can as long as you can in whatever directions you can.

The optimum case would be if they were under a lawn that is watered, otherwise
you just do what you can do.

From my point of view the drip system improves the ground while the XYL may
have a different viewpoint.

In my case, there is a small copper plate at the base of the antenna that
interconnects the ground rod with all the radial wires and is the ground
point for the tuner.

There is an old picture at http://mail.specsol.com/~jimp/ant_base.jpg

This one doesn't fold, but it would be no big deal to make that way.

The upside down trash can covers the auto tuner.

The low band loading coil is 1/4 inch copper tubing I happened to have wound
on a PVC mount and form. The switching relay is inside the coil form at the
bottom.

The loading coil was trial and error adjusted for best SWR on 80 without
the tuner in the circuit.

The PVC pipe going into the ground has the antenna coax and control lines
for the relay and auto tuner in it.

The ratty looking braid from the ground rod going up into the trash can has since been replaced with a #6 wire to the plate.

>Richard - Is there such a thing as a multi-band HF sleeve dipole or is
>this more of a VHF/UHF solution?

Hi Jay,

It is multiband if your tuner can pull the SWR into reasonable limits. However, you do NOT want the overall length of the antenna to exceed roughly a 1.25 wavelengths of the highest frequency you intend to multiband. This is for two reasons at that frequency:

1. Difficult to tune at 1 wavelength;
2. Radiation is directed up at a high angle if longer than 1.25 wl.

Please read Sal's perceptive comments about hi voltage exposure; and observe his statement about choking the line.

Futher, and this complicates the simple rules above, your sleeve dipole does not need to be made of equal length elements. This raises the prospects of another topic:
Vertical, Off Center Fed Dipoles.

As for building ground radials - skip that wasted effort. You have too little footprint available, and your ground isn't conductive enough to present that much loss. This is why I suggested the sleeve dipole.

73's
Richard Clark, KB7QHC

Yes.

Mine was mounted with the end of the bottom element within reach from the
ground. I lengthened just the bottom element experimentally with a simple
clip lead -- and that worked. Sometime "cheesy" works. :-)

And put your autotuner in the middle at the feedpoint.  Get yourself a
batch of 31 mix toroidal cores to make some chokes, too.

Cardioid has only a single null and is a "end fire" configuration. I
don't think (esp with short spacing) you can get as deep or narrow a
null as with a W8JK style antenna(short spacing, out of phase).

two 180 degree out of phase antennas can be very narrow, even with small
physical extent.

I favor the SG239... it's cheaper, and I can fabricate a weather proof
enclosure for a lot less than the price difference to the SG-237.  SG239
handles twice as much power, for all that's worth.

Electrical conduit, or PVC pipe with some wire on or in it are other ideas.

Conduit is about as cheap as you can get, and it's available in lots of
different sizes.  It's light weight too, so putting it up and down is easy.

Yes, it won't stand up to a hurricane.. but hey, you scrap your $10
investment in cheap galvanized steel and buy some more.

If you've got a tuner, you don't care about the absolute length of
anything. That makes life much easier.
You put in what you can for grounding. more is better, but whatever
works.. drip irrigation is for conductivity.

If you can snuggle one of your radials up against your concrete footing,
that helps Concrete is a fairly decent conductor because it tends to
hold moisture and it has large contact area with the soil. If you're
pouring a slab for a patio, put some wires in it.

You might want to consider a magnetic loop antenna -- easy to build and conceal.
Multiband might be difficult, but a small 1m diameter loop can easily cover 20 through 10m.
Google 'magloop antenna' and 'magnetic loop antenna'

Hello 1st post here.

I have made 20 meter delta loop.
What I am thinking is...
If I also make a 40 meter loop, and a 10 meter loop, putting them either
side of the 20 loop. As in the 20 loop in the middle. The 40 behind, the 10
in front.
With suitable spacing, all strung on 3 fishing poles.
Will this work as a directional beam of sorts hopefully all 3 bands.
I am hoping 3 traditional elements on 20,
even driven element on 40 /with 2 directors,
and on 10 with 2 reflectors.
I know the lengths of the director's and reflectors won't be as standard but
with a tuner does anyone will it work to a degree?

Just kicking the idea around.

Anyone done it before?

thanks' for any help or suggestions.

But, nothing; that's not the way things work. To get beam action, there is a very strong correlation between element size, element orientation, separation distance, and wavelength. Size and distance are on order of fractions of a quarterwave, not multiples of wavelengths.

>with a tuner does anyone will it work to a degree?

A tuner is for tuning (getting the SWR to a reasonable match). It has nothing to do with antenna directionality.

>I know the lengths of the director's and reflectors won't be as standard but

I think you'd need to model it out with NEC to see if it would work.

I'm unclear as to whether you're planning to have separate feedlines
for the three delta loops, or whether you were thinking of just
driving one of the loops on all three bands and having the other two
loops be entirely passive. If you are thinking of driving the three
loops separately, I'm uncertain what you intend to do with the other
two loops - leave the feedlines open, short the feedlines, or
disconnect the loops from the feedlines and short the loops closed at
the feedpoint.

You'll be facing a few significant issues, when trying to use the un-driven loops as directors / reflectors. For the sake of simplicity I'll assume that the un-driven loops will be purely passive loops of the expected length (e.g. no feedlines, or with the loop shorted closed at the feedpoint).

For example, on 20:

- The 10-meter loop is going to be only a half-wavelength long. It won't resonate (or be anything close to resonance), but will instead have a low radiation resistance and a very high reactive impedance. As a result it will probably be almost "invisible" at 20 meters, and will not carry enough currents to affect the pattern significantly.

- The 40-meter loop will be about 2 wavelengths long. Although it may be at (or close to) a second-harmonic resonance, the currents in it would not line up well with those in the fundamental-resonance 20-meter loop, and the effect on the main loop's overall radiation pattern would probably be quite weird.

Similarly, on 40, the two smaller loops will be highly reactive and thus almost "invisible". On 10, the two larger loops may resonate, but with current patterns which don't add well to that of the 10-meter loop and thus affect the pattern in weird ways.

There's another option: use some nested passive delta loops. Mount a second 10-meter delta loop (tuned a bit lower in frequency than you normally operate) suspended inside the 20-meter delta. Mount a second 20-meter loop (again, tuned a bit on the low side) inside the 40-meter delta. This would give you the effect of a two-element beam (radiator and reflector) on 10 and 20 meters, without affecting 40-meter operation significantly.

```

Take a look at the multiband quad beam in *The ARRL Antenna Book*.
That's what you would have to do for your multiband delta beam. Your
idea will simply not work.

Hard to know exactly what you're planning on building. Are you going to have 3 loops, one for 10, one for 20, one for 40 arranged in a row, sort of like rings on a post?

If you had a tuner on each loop, one might be able to get it to work. For instance, one can build a Yagi with 3 equal (or arbitrary) length elements and use L or C at the centers of the elements to get the phasing right.

The problem with 3 loops of radically different size is that the L and/or C might be impractically large/small to get it to work.

With a bit of work modeling, you MIGHT be able to come up with a single L and C per band for each element, so you could use some sort of simple "two relays per loop" scheme.

thanks for the input good fellows!
I'm obviously just playing around here.
I have looked round on the net and it's a cobweb antenna I was headed for.
I had the idea explained to me, but until I saw it, I had NO IDEA!
now it a tad clearer.

http://www.g3tpw.co.uk/

here is the website I found. clear as mud now... thanks again.

I'm helping a friend build a very simple portable VHF antenna for
hiking. Ignoring all the ladder line J-pole antennas on the web, I

decided a simple coaxial antenna would suffice. Remove 19.2" of outer jacket, peel back the braid over the outer jacket, tape, and instant 75 ohm coaxial dipole antenna. However, I'm not sure if the driven element cut length is the free space 1/4 wavelenth, as it would be with a metal rod coax antenna, or if I should include the 0.67 velocity factor of the coax dielectric covering the center conductor. Is it 19.2" or 12.9" for the driven element? My sense of smell says 19.2" but I'm not sure and can't find any specific references that deal with the problem.

Note: I would normally test this on the bench with a reflection coefficient bridge and sweep generator but I have another project going on the bench and don't want to move or touch anything right now.

Use the 0.67 VF on transmission line currents. Use VF =3D 0.95-0.97 for
antenna currents.

Hi Jeff,

Ah! The sleeve dipole re-emerges.

The exposed wire isn't much different from any other insulated wire
antenna. Air dominates the dielectric constant to the now remote
braid and the plastic ever so slightly shifts things. EZNEC includes

modeling insulated wire.

More's the issue of the dielectric coefficient of the braid pulled back over the outer jacket of your coax. Coupling issues to the insulated braid there too shift dynamics - and probably dominates the DC characteristic.

I usually cut long, and slowly snip the exposed wire until SWR improves. Choking the line would stabilize this.

First, the design you are looking is NOT a loop (nor loops).

The design you are looking is NOT a beam.

The design you are looking is NOT directional.

Aside from that, it has been around for a while, and satisfies many. You may be one who would be happy with it, but that is obscure until you tell us what you want to achieve without trying to shoe-horn in presumed solutions.

The simple explanation for the design you have linked to is that it is a "Fan Dipole." The fan is found in the common feed point (at the left) supporting paired wires for each band spreading (fanning) out. What makes it unusual is that it is wrapped into a box-like footprint (without the ends meeting, look closely at the photo). The wrapping also changes the usual dipole radiation characteristic from dipolar (radiating in two major lobes) to nonpolar (radiating in all directions).

Do you have a call sign?

Another solution I've tried is to put a choke on the line that I can slide along its length (and later tape down). I then put a connecter at the far (antenna) end of this line. I then put a bare/insulated wire on a female connecter and mate the two. This preserves the line from stripping and peeling back.

I cannot vouch how effective this is as a "Sleeve Dipole" in all the standard characteristics. The Choke Z would have to be very, very high to electrically snip the lower end to the right length to tune it. Another choke a quarter wave away would be necessary. All doable, certainly, but ad-hoc.

Do you have a call sign?

no, no call sign, I have just been given a shortwave radio
Realistic DX-300 Shortwave Radio Receiver.
I was told I could just hang a good length of wire out in the tree and it
will work.
It does but thought I would have a bit of a go at improving things.
I read a lot on the ham radio news groups, but you can get bitten when you
ask a question,
so thought would try here. I quite like listening to ham types, and the
techno talk, not too keen on the 5/9 next please bust busy contacts, but
when people have real conversations about making stuff its good listening.
. thanks anyhow.

Jeff Liebermann <jeffl@cruzio.com> wrote in
news:lu9j27drlnanelqf4mp7bmkr390n17ob20@4ax.com:

Jeff,

You are treading down a well worn path.

There is a flaw in thinking that the shield of the coax below the bottom of your nominal dipole does not carry significant current on the outer surface. Whilst you are trying to account for the current distribution on the nominal dipole, you are ignoring the common mode current on the feedline.

The antenna will 'work' and you may be delightedm but if you expect that it will have very low VSWR based on formula dimensions, I think you will be dissapointed.

You might obtain better feedline decoupling by some form of common mode choke.

The failure of the sleeve to effectively decouple the dipole is the reason why several antennas don't work as thought. King gives some hints that the relative diameters of the conductors bears on operation.

Owen

I made a sleeve dipole cut for 375 MHz for listening to the Blue Angels in flight at NAS Miramar, c. 1992. It worked, but, heck, we could see them most of the time. I was in Coat Hanger Territory. By the way, the Blue Angles say very little in flight. :-(

This thread got me thinking. If three or four tuned radials were added, would this be a better approach? Yes, I realize it gets toward a lot of the standard commercial monopole antennas, with their 45-degree-down radials. I mention this because such radials could be added and still keep the builder in comfy Coat Hanger Territory -- that is, a very light, casual, cobbled-together antenna -- but something that works a bit better and helps the decoupling.

Frankly, I understand what it is to buy something and what it is to build something; I'd rather build. It keeps me off the street. :-)

Go with your sense of smell. The velocity factor of coax only applies
when the shield is positioned where it is designed to be. Let us know
how it fares.

A set of radials helps to decouple the feedline, in this case, you would place them a quarter wave below the bottom of the sleeve.

Ok, you have noted commercial implemenations of this idea... yes it is done. The quarter wave between the radials and the bottom of the sleeve carries significant current, ie it affects the pattern and gain.

And still, decoupling is not perfect, though much better.

Whilst the OP's design looks like it is simple, in my experience it is not. Whilst I have had a lot of success with coaxial dipoles where the sleeve was three times or more the diameter of the inner element and substantially air dielectric, I have had little success the the cheap and nasty approach of applying braid over a vinyl jacket and trying to adjust it for low common mode feed line impedance and low VSWR. I am not saying it is impossible, just not as easy as a ground plane!

>on the nominal dipole, you are ignoring the common mode current on the
>feedline.

Agreed. The feedline should be decoupled, which one can do by wrapping a few turns into a coil and tied together with tie wraps. Another method is a 1/4 wave decoupling sleeve further down the coax cable.

>The antenna will 'work' and you may be delightedm but if you expect that
>it will have very low VSWR based on formula dimensions, I think you will
>be dissapointed.

Well, putting a 75 ohm antenna onto a 50 ohm system results in a minimum VSWR of 1.5:1 assuming the coax is cut for some multiple of 1/2 wave electrical length. Also, most HT's are designed to tolerate the fairly miserable VSWR presented by rubber ducky antennas and body proximity.

In this case, the problem to be solved was rather mundane. A friend was in the process of packing for a weekend camping trip with the kids. His 13 year old daughter apparently had lost the rubber ducky antenna from her Yaesu FT-60r. Rather than borrow an antenna, or build an adapter kludge, he decides it's time for her to build an antenna. They found some SMA cables, and proceeded to make a simple coaxial sleeve dipole. However, there was some debate over the cut length of the driven element because of the presence of coax dielectric. I get a hasty email with the question and discover that I really don't know the answer. So, I posted the question here. We'll find out how it worked when they return.

Whether the home made antenna is optimized for best performance doesn't seem to be important in this case. Any reasonable antenna is better than a rubber ducky, so she should be fine (assuming she doesn't lose another antenna).

>You might obtain better feedline decoupling by some form of common mode
>choke.

Yes, that will help (as previously noted).

>The failure of the sleeve to effectively decouple the dipole is the
>reason why several antennas don't work as thought. King gives some hints
>that the relative diameters of the conductors bears on operation.

And the answer is not a simple as put by some. Particularly, if you had in mind that the sleeve should be an electrical quarter wave to current flowing on the outside so forming half of a centre fed dipole, and an electrical quarter wave on the inside to form a quarter wave s/c stub, the presence of high permittivity dielectric on the inside prevents those both happening together... so you compromise, like discarding the centre fed concept, tune the s/c stub for resonance (max decoupling, and the sleeve will be less than a physical quarter wave), now tune the top part of the dipole (it will be a bit longer than a physical quarter wave) for lowest VSWR on the feedline.

> I get a hasty email with the question and discover that I

To some extent, everything 'works'. Just stripping a quarter wave of
shield off the end of a length of coax probably 'works' about as well.

>

Indeed, it seems that for most modern hams, performance isn't an issue
or of interest.

Owen

Will it work? Yes. Will it be a very good antenna? No, but you
didn't expect it to be, did you? It's possible for it to be better
than the typical rubberducky though. That's the whole point, isn't

it?

I haven't. I also know that using the available RG-316 or RG-174 coax cable is not going to yield optimum results. For a commercial product, suitable for general consumption, such compromises are not a great idea. However, for the purpose intended (short notice replacement of a lost HT antenna suitable for a camping trip), in my never humble opinion, is totally adequate. As long as it throw RF in the correct direction, and doesn't cause the transmitter to shut down from excessive VSWR, it should suffice.

>And the answer is not a simple as put by some.

With all due respect, the answer is NEVER as simple as the common wisdom and practice. I just went through a similar mess in rec.bicycles.tech, where I contended that many of the common design practices found in todays bicycles are not sufficiently optimized. When success is measured in milliseconds and profitability in tenths of a penny, then good enough is never really good enough. Antennas should all be silver painted, made from Litz wire, use Teflon insulators, suspended air dielectric coax cable, and gold plated connectors. That should squeeze the last 0.000001dB out of the design. One can always make an antenna a little bit better.

However, I don't think the 13 year old will notice. Similarly, 90% of the hams using a sleeve dipole coax antenna will notice. The real question is "what is good enough". In this case, it's the ability of a 13 year old to build an antenna on short notice, that works at least better than the stock rubber ducky, with available parts, and probably keep her out of the parents way as they load up the camper.

>Particularly, if you had
>in mind that the sleeve should be an electrical quarter wave to current
>flowing on the outside so forming half of a centre fed dipole, and an

>the presence of high permittivity dielectric on the inside prevents
>those both happening together...

Huh? I thought (err... guessed) that the dielectric only has an effect if it were between the conductors. The grounded half of the dipole formed by coax braid has the vinyl outer jacket forming a dielectric. I presume this is what you consider to be a problem. Worse, the jacket can be various grades (flooded, plenum, buriable) with various dopings (UV proofing, gel filled). In general, it seems to shorten the electrical wavelength. This is usually not a problem because expanding the diameter of the coax braid, as it's folded back over the shield, also mechanically shortens the braid. In the 2 or 3 such antennas I've built over the years, I've randomly shortened the braid. What makes such arbitrary design decisions function is that the dipole has a rather large operating bandwidth. One can be incredibly sloppy and still end up with an acceptable antenna.

>so you compromise, like discarding the centre fed concept, tune the s/c stub for resonance (max decoupling, and the sleeve will be less than a physical quarter wave), now tune the top part of the dipole (it will be a bit longer than a physical quarter wave) for lowest VSWR on the feedline.

I must confess that I haven't bothered to try optimizing such an antenna, while you obviously have made the attempt. What I usually do with crude antennas is to attach one of several reflection coefficient bridges in my pile or a directional coupler and some diode detectors, sweep generator, and scope, and just play with the dimensions until it works. Calculations, NEC models, and theory are great, but I prefer to see the results on some test equipment. (For 2.4 and 5.7Ghz antennas, I have a rather marginal test range and transfer standard, which are suitable for estimating the gain of the antenna).

>> I get a hasty email with the question and discover that I really don't know the answer. So, I posted the question here. We'll find out how it worked when they return.
>
>To some extent, everything 'works'. Just stripping a quarter wave of shield off the end of a length of coax probably 'works' about as well.

That's probably what she ended up building. If she can talk into the local repeaters, it's good enough.   In this case, the 13 year old antenna builder is probably not up to doing much more than measuring, removing the outer jacket and peeling back the braid. I was going to suggest adding a decoupling sleeve (using aluminum foil duct tape), but decided that would be too much for a quick build. Maybe when they return.

I forgot who rammed this down my throat when first got started in engineering.... "The secret to engineering is to know when to stop engineering and start building". It's a moving target, that has many implications, but my method is that when it meets the "suitability for purpose" criteria, you're done.

>> Whether the home made antenna is optimized for best performance doesn't seem to be important in this case.
>
>Indeed, it seems that for most modern hams, performance isn't an issue or of interest.

That's also true for 90% of bicyclists. 90% of the bicycling public do not race their bicycles. Similarly, 90% of the hams probably are not optimizing their antennas and designs to what can theoretically be achieved. It doesn't take much to look at an existing design of literally anything, and think of a better way to do it. I do this all the time. (Former ladyfriend called it the engineering mentality and claimed it drove her nuts). Whether the average ham wants or needs that last dB squeezed out of the design is problematic. If I were doing moonbounce or microwave DX, where every fraction of a dB is important, I would certainly be into such optimizations. However, for yacking on the local repeaters, almost anything will work.

I'll probably steal a few of your ideas and comments in order to build a "better" coax cable dipole, if she returns with an interest in how it works, or how to make it better.

Hello,
I want to put up a center fed dipole for 75 meters. Trouble is, my lot is not large enough to run the two legs without any bends.
My tower is in the center of my lot and is 60 feet at the peak, and is 40 feet to both ends of the lot.
What would the best solution be without using coils to "shorten" the antenna?
I've had some luck by "dog legging" each leg of the dipole, but have not gone past 200 watts power for fear of a arc.

Thanks,
73, W6IML

Hello Dave,

Having some bends in it (or a small vertical part) will result in minor change, as you have sufficient straight length (your 80 ft lot).

You may need to increase the overall length somewhat and the input impedance may reduce somewhat. If the ends run vertically and are close to ground, length reduces mostly.

With kind regards,

Wim

Using only the wire, get as much of the middle as high as you can and put the last 20 or so feet of the antenna anywhere you can as high as you can get it. Most of the radiation of a dipole is from the center part of the antenna.

Try to keep the angle at the center as large as you can and not less than 90 to 120 degrees if possiable.

Eagle-

A quick calculation suggests you could put up a 144 foot inverted V
dipole with no other bends.  You could elevate the ends or lower the
center to fit your antenna.

A Ham buddy 's son just got his General ticket, and asked for my assistance in making a surprise contact with his Dad for his first HF QSO. He had bought a nice 100W HF rig with an auto tuner, and an 40M-10M coax fed multi-band doublet antenna that was to be put in his attic initially. He lives about 100 miles from his Dad.

I thought this was really cool, so I said I would set the whole thing up. Suggested 80M early evening for that distance would be best bet. He told me the auto tuner would not tune the 40-10 antenna on 80M (5to1 SWR). He then asked (here is the magic part) what he could do in 1 hour to get the antenna to tune on 80M.

I told him to short the 40M loading coils, and add enough Home Depot wire to each end so that the auto tuner was happy. He had a 100' extension cord that he cut up and got the auto tuner happy <1.5 swr.

At QSO time he could hear neither his dad or myself, and we gave up. Not to be discouraged he removed the shorts and additional wire, the tuner provided a 5:1 swr, and he had a nice QSO with his dad. He also stated he heard a lot more signals than before.

Other than the obvious (he was mistaken in what he reported to me) any ideas as to what went wrong? I don't think he will ask for any more advice from me.

Gary N4AST

Which goes to show that power is not necessary for communications. (If at 5:1, you are still getting half the power out into the �ther. Let's call it 10:1 - that's still 30W out across 100 miles.) Nevermind the smoke.

>Other than the obvious (he was mistaken in what he reported to me) any
>ideas as to what went wrong?

You mean the shorted coils and the extra wire? (Maybe he should have turned it off, and then back on again - Oops, standard IT advice.)

Haven't a clue.

>I don't think he will ask for any more

Propagation changed I bet. I strongly suspect the antenna
had nothing to do with it, and the extra wire and coils
bypassed was most likely the best system regardless of
the results seen when trying it.
It was most likely a fluke of nature, and I imagine
your antenna really was the best of the two.
If the band is kaput, nothing will work. 80m can get
really funky early in the evening. Have him try the longer
antenna a bit more at different times of day before discarding
it.. It should be fine. I have trouble seeing it being worse
than the shorter version with the less favorable match.

You forgot to offer burnt offerings to the radio propagation gods.

>I don't think he will ask for any more
>advice from me.

80 meters at 100 miles is in the range of the NVIS propagation. 25
miles is about the limit for 80m ground wave, and 300 miles is about
where sky wave starts. The problem with NVIS is that it's really
picky about the height of the antenna above the ground. I don't have
very much NVIS experience to offer any guaranteed suggestions on how

to make NVIS work reliably. I assume the kid will be talking to his father regularly. My limited and unscientific tinkering empirically determined that the NVIS horizontal antenna wire has to be fairly close to the ground. A dipole that close to the ground has a fairly low impedance. See "height above ground" section:
<http://www.w0ipl.net/ECom/NVIS/nvis.htm>
My guess(tm) is that with the antenna near the ground, most of the RF goes straight up, which is what you want for NVIS, while an elevated antenna delivers more RF towards the horizon. There are plenty of web sites expounding on NVIS antenna and propagation worth reading. Tell the kid what you think happened, but let him do the research and tinkering.

Not really. Just as long as the antenna can radiate upwards,
the height above ground is fairly non critical. IE: at dipole
at most any practical height will still be fairly decent at NVIS,
where as the usual vertical won't be. I've seen dipoles at
120+ feet still be good for NVIS on 75m. And they will be
better at long paths than the lower ones.

NVIS is sky wave, it's just high angle sky wave. I've often
seen good NVIS at 25 miles or even less. And often seen poor NVIS
at 25 miles. And it can flop back and forth in thirty minutes
time. Maybe quicker in some cases.
75/80 meters can get pretty squirrely in the early evening.
It's changing from the usual short daytime sky wave, to the
longer night sky wave. And you never really know what is
going to happen for sure. I've seen short distance NVIS
propagation go from strong to nil in thirty minutes time,
and visa versa. Lots of times, it will start out pretty good
early to short distances, then go kaput for shorter distances
for a while, maybe an hour or three, and then come back later
in the evenings. I see this a lot in solar cycle minimum years
in the winter. The MUF can actually drop below 4 mhz for periods
of time between various distances.
When that happens, all the close NVIS stations will be kaput,
and about all you hear is longer path stuff..
And then two hours later, it will come back, and you'll
hear the closer stations again. It generally gets more
stable as far as the F layer, the later it gets..
Usually by midnight or so, things are starting to get
fairly stable. But even that is no guarantee that
the short skip will be good.
Sometimes when the short NVIS skip goes south on 75,
we would jump down to 160m to be able to continue
talking. Then a couple of hours later when 75 came
back as far as short paths, we would go back.
Even on 160m, it's not unheard of to skip over people
at various times. There is a often a minimum skip zone
even on that band when using sky wave paths.

It's just like rolling the dice. I spend probably 85%
of my time operating on 80 and 40 using NVIS paths, so
pretty familiar with the usual antics the bands pull.
I'm almost certain that at the time he tested the first
longer antenna, the band was kaput to that distance,
and in the time it took him to redo the antenna and
get back on the radio, the propagation came back to
those short distances. Seen it a zillion times.. :/
I'm fairly sure the antenna wasn't the problem.
In our usual regional NVIS lingo, the band was boogered
up.. :| I think the antenna will be found to be innocent
once given a fair trial.

The modern explanation to modern hams is that an antenna tuner is there to keep the rig "happy". Modern folk are very busy people, they just don't have time for understanding, but personification of these inanimate things is apparently appealing.

Your anecodote demonstrates though how inadequate that explanation is, whether happy rig or happy ATU.

I understand your feeling that your pride has taken a bit of a dent. Well, part of the territory when predicting antennas eh!

Next thing, someone will market a happiness meter, an SWR meter rebadged and rescaled with a percentage happiness factor. Ultimately, the slow to respond rig manufacturers could incorporate a happiness meter under the covers, perhaps a range of LCD emoticons for those who don't want to think about percentage happiness. You could turn on a proper multimedia interaction, big groan for SWR>5 etc, big cheer for <1.2... bit like those terrible computer golf games "can't be too happy about that one!!!".

I will respond in a couple of hours, but in the meantime, please clarify
that everything between the ATU and LazyH is up for consideration.

What impedance line are you using?

Do you feed the antenna midway between the elements of at one element
(branch or distributed feed)? What do you think the feed point impedance
is?

What band(s)?

I am using 450 ladder line. The Lazy H is center fed with 1/2 wave
spacing between the top and bottom elements and the elements are 1/2
wave elements. 450 ladder line is connecting the top and bottom
elements. I am not using the expanded Lazy H version. This is the
classic center fed Lazy H design as shown in the ARRL antenna
handbook. I only intend to use the antenna on 10 meters. I don't
know what the exact impedance is (sorry). The Lazy antenna is about
50 feet off the ground at the top wire. The amplifier I want to use
with the Lazy H is a Drake L4B with two Eimac 3-500z tubes.

Ok, if we define the feed point to be half way between the dipoles, you ought expect that the feed point impedance is relatively low, some where of the order of 50 ohms, give or take some reactance and it is a fairly balanced / symmetric load. Note that the feed system to each dipole is a tuned length of transmission line, that makes this a narrowband feed system.

So, your challenge is to deliver the transmitter a nominal 50+j0 load.

Re the ATU's integral ATU, always regard them as likely to be unsuitable.

Let's regard that, integral balun aside, your ATU is probably capable of matching a fairly wide range of impedances at 10m with reasonable efficiency.

If you objective in using a balun is to minimise feedline direct contribution to radiation, your objective is to try to force equal but opposite currents in each conductor.

An ideal voltage balun will approach that objective ONLY with a perfectly symmetric load. If you think you have a perfectly symmetric load, it is probably because you haven't measured it.

An ideal current balun will approach the curent balance objective irrespective of load symmetry, so it is a better choice for your application.

Why do you need a 4:1 transformation? Depending on your feedline length, the impedance presented to the ATU may be as low as somewhere round 50 ohms, and perhaps as high as several thousand ohms. It might seems good to transform several thousand ohms by a factor of 4... but transforming the lower impedances by a factor of 4 exacerbates ATU losses.

Since wavelength is short, I would be inclined to try to use a feedline length of an integral number of half waves, and an effective 1:1 current balun at the ATU. This minimises working voltages within the balun and ATU (reducing risk of flashovers), without driving high losses in the ATU are very low impedances.

If you think about your own requirements, and finding a solution that fits, you will do better than Googling up HamUniverse articles and the like.

Owen

When I calculate the feedline length am I correct in assuming that I
need to take in to account the velocity factor of the 460 ohm ladder
line?

Yes Michael, it is the electrical length that is important.

You can use TLLC http://www.vk1od.net/calc/tl/tllc.php to calculate the approximate length of Wireman's ladder line to give you some idea. If you specify the length in wavelengths, the results will show you the physical length in metres. Divide that by 0.3048 to get feet.

The length is not terribly critical, you are just trying to feed the thing near a current maximum rather than a voltage maximum.

If your balun requirement becomes an effective current balun that need
only suite 10m, then a number of options spring up, but a ferrite cored
balun similar to a general purpose HF balun, but with slightly less
turns is likely to give superior performance for the high end of HF.

If you want to read more on the reasoning behind my recommnedations, I
can give you some links.

Owen

Why, yes. I usually get crushed.   I have occasionally been lucky.

Do tell why you ask. Dare I guess it has something to do with an
ignorant comment or two I've (probably) made about antennas and/or
takeoff angle? ;-)

I did mean "down a few dB," by the way, not "down a few s-units."

http://www.eham.net/articles/23758 is interesting.

I contest occasionally. Mostly on 6m and usually as part of a team
doing the ARRL QSO parties and the similar contests from other sources.

It's really fun because of my center of the continent position, one hop
from almost everywhere.

This year's field day was a ball. I did over 200 Qs on 6m in 8 hours
with 80 watts and 8dBd at 25 feet. 55% of the contacts at a 4A contest
site at the time 6m finally collapsed (around 10PM local).

We had to tear down at 6:30 AM due to thunderstorms.

The reason I'm asking is that 'm considering putting up a 10 dipole in a
portable location.

My first week with my HTX-100 mny years ago was a blast, and I've
enjoyed operating ever since. Most frustration: Hearing a French
Polyneasia at 10 over S9 and being unable to get through due tyo a
couple of hundred Califonians (onw skip zone closed) with beam antennas
and kilowatt amplifies. 25W into a dipole just couldn't cut the mustard.

Good news.

I tried eternal september.org on Win XP in my shack
and it works. This response is through
them using the Outlook Express client, which I
was using before my ISP shut off its NG server.
Good tip. Thanks.

I notice the spam distractions are absent. Good.

Next trick, getting it to work on the iMac, for which I
do not currently have a newsreader. (Betas of the
next Apple OS are said to have major enhancements
to Apple Mail. Fingers crossed for that to include
a newsreader.)

Regarding your login hassle, it is avoidable. My
news client does it for me automatically and
displays my subscribed groups as folders.

True, Outlook Express is bad, but not ALL bad ;-)

I also tried september.org using the XNews client which offers much richer filtering than you get through most newsreaders... and doesn't have the bottlenecks and stalls that Google Groups has, with or without its new interface.

Why not just use a(n electrical) half wave loop of coax if you are only using
it on 10metres? Or even just a Pawsey stub for a balun and match elsewhere.
You can do a lot of (single band) matching with just a quarter wave of open
wire line with shorts/open circuits and taps.

Dear Group: Very good observation from Owen - as always.

Time for an story, which I hope illustrates several things:
Back over 50 years ago, my great pal at The University (if you are from this part of the Midwest you know exactly what I am indicating) W8BZB had a small, English car. This was only possible for an undergraduate because he lived in town. He installed a little 10 meter AM rig in the car that used tubes and a motor-generator set to get high voltage. Worked into Europe like Gangbusters. One day we got to examining the rig and I noted that the tubes all had 12 volt filaments and the generator was for 12 volts too. His car had a 6 volt electrical system. Anything can work.

Thus ends the lessor about the first rule of HF antennas. 73, Mac N8TT

P.S. The first rule of three-phase motors is never to tighten their couplings until you have verified direction of rotation.

Hi John,

Perhaps I might answer by nominating some that are more dependent on ground.

The classic case would be a monopole worked against real ground, meaning having one terminal of the feed line connected to the dirt in some way.

A centre fed dipole rigged very low to real ground is more depended on ground than one that is higher.

My experience is that if you don't have the time or resources to install a substantial ground system, avoid antennas that depend greatly on that ground system for performance. Driving a short conductive stake, or running a wire along the surface, or running a wire into a body of water does not make an effective ground system for these purposes.

I recently had QSO with a field station on 40m at about 500km distance. Initially he had a half wave dipole lying on the ground, and was somewhat surprised that I could work him with 100W from his tx. He raised the dipole to 5m (15') and we tried 50mW SSB. He reported that I was essentially noise free at that, but I could not reduce power any further.

We prove time and time again that anything "works", but an antenna less dependent on the ground usually gives more consistent performance.

Owen

I've been using Eternal September for about a year, ever since Telus, our local telephone company from which I have ADSL connection to the Internet, dropped Usenet. Like Macs and Subarus, Eternal September just works.

> I notice the spam distractions are absent. Good.

Their spam filtration is excellent. But see below.

> Next trick, getting it to work on the iMac, for which I
> do not currently have a newsreader.

Get MT-NewsWatcher 3.5.3b3. Ignore the beta designation. It too just works. It's Universal, so it worked on my wife's old PPC 2005 iMac and my old PPC 2001 Mac tower both running Mac OS 10.4 (Tiger), it works on our 2007 MacBook laptop running Mac OS 10.5 (Leopard), and it works on my newer 2010 Intel iMac running Mac OS 10.6 (Snow Leopard). There is no reason to think it won't work fine under Mac OS 10.7 (Lion) since it does not rely on PPC code and thus won't need Rosetta, which will be missing in 10.7.

It has excellent filtration capability, though with Eternal September you will have little need for it. I mainly use it to avoid having to look at the postings of a few kooks on this newsgroup.

It automatically connects to all your selected newsgroups when you fire it up.

It's a descendant of the original NewsWatcher program, which came from
John Norstad, who wrote the legendary Disinfectant program, so valuable
in the days before Macs started using Unix labelled as OS X. You can get
MT-NewsWatcher any number of places, the easiest being at MacUpdate.
It's donationware, and well worth a modest donation.

David, ex-W8EZE

Then again, I'm not saying which is which.

It's not hard to tell though. Good advice tends to have the ring of truth to it. It's something you can reference, can duplicate, and at some point makes sense.

The other sort might be mystery physics, like little particles that jump off your antenna to another, the discarding of everything past Volta, or magical 3 foot antennas that work better than anything else.

Then again, I guess I just did say which is which.

So is this like the aether that acts as a transport medium, or is it
like quanta, that pop into and out of existence?

And that's where I have the issue. Use of the two terms like that is
confusing. I find that some like to invoke the term as some sort of
vindication of previous ideas, some just invoke a superficial
resemblance. I remember when I first learned of quantum soup, I
immediately thought of aether, but after ten seconds or so, I figured it
was a very superficial resemblance only.

It's still not aether, it's an awkward prediction of infinite energy.

As incredibly cool as I think that would be, I suspect that we're going to find that there is an equal and opposite effect going on.

If it's real, then Arthur C Clark predicted not only a whole lot of energy, but a heat crisis to boot. Know how that would happen?

Why do balun builders always use "enameled" wire? Won't regular electrical insulated copper wire like they sell at Lowes or Home Depot work? Since copper is copper what is the benefit of enameled wire over other types of insulated wire? Also is there a benefit of using solid copper wire over stranded copper wire to build a balun?

> Why do balun builders always use "enameled" wire? Won't regular electrical insulated copper wire like they sell at Lowes or Home Depot work? Since copper is copper what is the benefit of enameled wire over other types of insulated wire? Also is there a benefit of using solid copper wire over stranded copper wire to build a balun?
>
> Michael Rawls
> KS4HY

Because the windings on a balun is not just turns on a core. They are transmission lines of a specific impedance. Wires of a diameter must be a certain distance apart to make a line of of the desired impedance. If the line is supposed to be 50 Ohms they need to be close together, too close for the thick insulation on house wire. Stranded wire is harder to wind on a ferrite core and maintain the spacing that is needed to make a good balun. Just remember that baluns are not transformers in the classic meaning of the term. They are made of sections of transmission lines. For example a 4 to one balun is made of 2 100 Ohm lines that are connected in parallel on one end, 50 Ohms side and in series on the other end for the 200 Ohm side. The common mode impedance keeps one end from seeing the other at RF frequencies. You can not see this with a Ohm meter!

Change the "or" to "and" and you've got it. It is quanta that pop into and out of existence that acts as a transport medium for EM waves. EM

waves cannot propagate without "it" as a medium. That's why EM waves cannot escape the universe - witness the 12+ billion year old background radiation still propagating through the quantum aether to this very day.

The don't ALWAYS use enamelled wire, but yest, it is very common.

I previously reocmmended a 1:1 current balun to you, so I will answer your question in that context. (I do note though that someone has since recommended a voltage balun.)

If you are looking for a 'general purpose' balun to use with an ATU, you should be more interested in a balun that can withstand high voltages than close to ideal impedance transformation.

ECW is a relatively poor choice, and Thermaleze ECW which has a higher nominal voltage rating seems not up to the task at extreme loads. PTFE sleeved ECW or PTFE insulated flexible wires seem a better option for extreme loads.

Stranded wire does have higher loss than an equivalent circular conductor... but losses in a current balun in a practical antenna system are usually mostly due to common mode current causing heating of the core, ohmic losses in the windings are usually much lower and insigificant... though they do commonly feature in published specifications.

Again, more info is available if you want the links.

Owen

I infer that a perfect vacuum wouldn't propagate EM waves. If a clear glass cube (or other hollow structure of your choice) could be evacuated completely, what would I see if I looked at it? Does light propagate through it? Would objects inside it disappear from view? The cube appear to be painted black on its inside walls?

===

I see "quantum soup" referred to in the context of the time immediately after the Big Bang. How would you describe the latter-day quantum soup? Photons? Something else? Is it of constant density or variable? If variable, is there an optimum density?

The concept of "no EM waves propagating through nothingness" allows for the existence of other Universes, about which we can know nothing unless one begins to overlap our own. Even then, it might take billions of years for their EM waves to reach us. Interesting to contemplate.

?

After the time when the universe changed from being opaque to being
transparent to EM light waves,  a dilution of the quantum soup has
occurred. The increase in the wavelength of the Big-Bang energy is
proportional to the expansion of the universe. When the quantum soup
gets diluted enough to cease its expansion pressure, gravity will take
over and the universe will collapse into another singularity - ad
infinitum - just as it has "always" been. The quantum soup is like a
spring that releases expansion energy for a time and then stores
collapsing energy for a time. What could possibly have more inertia
than the entire universe?

P.S. It's hard to talk about the passing of time when time is known to
cease to exist during a singularity. "How long does a singularity
last?" is a nonsense question because time is undefined during a
singularity.

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

One significant omission, requiring immediate updates, for this article |
is that it does not mention newer amateur radio newsgroups created since |
it was written, including: |

```
 rec.radio.amateur.antenna                                                     |
 rec.radio.amateur.boatanchors                                                 |
 rec.radio.amateur.dx                                                          |
 rec.radio.amateur.equipment                                                   |
 rec.radio.amateur.homebrew                                                    |
 rec.radio.amateur.moderated                                                   |
 rec.radio.amateur.space                                                       |
```

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

John S <sophi.2@invalid.org> wrote in news:ivb170$m0l$1@dont-email.me:

> Oh, yeah?

Simply, the conditions for steady state analysis are not satisfied by TV
bandwidth modulation on a long feed line.

This is the reason why some matching schemes that are quite suitable for SSB telephony on feedlines of a few hundred metres are not used with TV on long feedlines.

Owen

Hi Guys,
  I'm looking over the files at;
  http://groups.yahoo.com/group/thedallasfiles/
These antennas are mostly for the AMBC band.
  The author doesn't allow discussion on the site,
I wonder if anyone else has viewed these files and
has interest in the antennas and wants a discussion group.
            Mikek

  Do you mean you don't have an interest in the subject
or do you mean you have a better antenna for the
AMBC band?
   If you have a better antenna, let me know, I'm ready to start
building. Ideally I want to rotate a flashlight beam...
but I'll settle for rotating a wide aperture null.

Hi Mike,

The subject is Dallas Files, right?

What does that mean?

I've no interest in playing games with the author who refuses to engage in dialog simply to access files of unknown content. Apparently given the dearth of participation, neither does anyone else. With the absence of discussion at the author's site, there is no interest there either.

Now, if you care to describe what you have come to learn, that is another matter. I presume by implication alone that this is about small, beam stearable, receive-only antennas. Unfortunately, there's a lot left unsaid.

  Hi Richard,
   Ya, the author has no interest in engaging, he just posts what he has
learned. The site was recently moved to Yahoo and is only about 2 months
old. As for the absence of discussion on the site, it's not allowed, so
that is hardly an indicator.
  Yes, I'm looking a steerable receive only arrays for the AM broadcast
band. Myself, I want one that will fit on a 150ft lot.
  Sounds like you didn't look at the site so "what is left unsaid."

                   Thanks, Mikek

Shot fired when neighbor feud escalates

July 05, 2011 1:01 PM

PINON HILLS � A Pinon Hills man is behind bars for attempted murder after allegedly shooting into his neighbor�s home following an argument, San Bernardino County Sheriff�s Department officials said.
Baron Smith, 47, became involved in an disagreement with his neighbor Sunday and it escalated, Jodi Miller, spokeswoman for the sheriff�s department, said. According to reports, the neighbors had been feuding for some time. �This is an ongoing fight and this time it accelerated to that level,� she said. Authorities received several reports of a man shooting toward a house in the 2500 block of Olivera Road at about 6:30 p.m., according to Miller. When deputies arrived, they learned Smith had gone back to his home across the street from where the shooting had taken place. Officials went to the home and arrested Smith.
The Pinon Hills man was booked into Victor Valley Jail for attempted murder. He�s scheduled to be in court Wednesday.

--

The unnamed individual is Frank Rossio older brother of screen writer Terry Rossio.

On 3840kHz the below between July 1 and July 11 between the hours of 9:00PM (PST) and 4:00AM (PST) all the below individuals below

KI6GPR, (Cosmo - John), of Santa Clarita, CALIF
NO6L , Charles (Chuck) G Ruff of Tehachapi, CALIF
KI6DKV, Noel W Burman of North Hollywood,CALIF
KK6FR, Frank Rossio of 2540 Olivera, Phelan, CALIF

have stated that Frank Rossio (kk6fr) will own Baron Smiths property, and all have used a gang like character assassination against Smith. There is some collusion with the individuals above and Frank Rossio to illegally obtain Smiths property.
The individuals above should be investigated.

ALSO consider

point one - Rossio owns the defunct FG Bestcommunications, a company that entitles him to obtain dangerous chemicals and may be fraudulently using his business license to claim tax exemptions. In August of 2010 AD8Q Kevin Caprio, drove to Phelan and purchased some equipment from kk6fr then returned back to Arizona dropped dead shorty thereafter after complaining of massive headaches.

point two - ke6ynh, Tom from San Diego got into a big argument with

kk6fr and no6l about November of 2010 on 3840kHz. Both Frank Rossio and Ruff threatened to drive down and kill Tom, well in December 2010, passed on from mysterious causes. Ironically when the two silent keys died, Frank exhibited no apathy and even praised their deaths. In regards to Smiths arrest he bragged about it and mentioned "his (Smiths) property is as good as gold his (franks)."
Something is going on! Frank Rossio and his clan of cohorts needs to be investigated. KK6FR is nothing but a liar, braggart, punk, who threatens people and exhibits a schizoid personality, one trait is his lying and contorting stories, no different than a con man!

DO NOT BELIEVE EVERYTHING FRANK ROSSIO SAYS IT'S A
RUSE. IF YOU ARE A HAM YOU'D BE ADVISED TO AVOID ANY QSO
WITH THE ABOVE INDIVIDUALS.

Hi Mike,

As I said, nothing there but a vague suggestion of the topic heavily cloaked in an admonition.

> Yes, I'm looking a steerable receive only arrays for the AM broadcast
>band. Myself, I want one that will fit on a 150ft lot.

Is that 150' on a side? 150' long?

There are any number of ways to construct variable delay lines. A little bit of computer control will pull their outputs together to form beam steering.

Planting the antennas is simple and allows for testing of any of those many ways to construct variable delay lines. Those designs themselves have various trade-offs for issues you need to prioritize and pronounce. The antennas don't need to be in any particular, regular pattern as that would be accommodated by computer alignment.

If you choose to go manual steering, with analog variable delay line designs; then, yes, having a regular pattern of element layout would reduce complexity.

How many antenna elements? At least three, I would suspect. From there on it is a matter of how well you can resolve the various delay angles for steering a broad beam angle. Increase the number of elements and the beam angle gets progressively tighter. You don't say how much directionality you want, but it will be intimately correlated with this count.

The delay lines will have to be tolerant of mutual coupling - better yet, they should not perturb the existing mutual coupling at all. Good isolation amplifiers between each element and its delay line before going to a summing amplifier would seem a solution. Tracking between delay lines will affect beam width. More elements will require tighter tracking.

Then there is something simpler, an Adcock Antenna and the Bellini Tosi Antenna (about 100 years old, but does the job too). There is the Krug (Wullenweber) antenna. They are all symmetrical designs that simplified the manual, analog delay lines design.

In the end, they all comprise the same fundamentals. If you cannot support a symmetrical design, that is your primary limiting factor. If you can digitize the delay lines, then symmetry can be synthesized and the antennas can be placed physically anywhere limited only by the resolution of digital sampling rate.

First there was a fire in the 300m IJsselstein (lopik) tower, some hours later there was a fire in the "Smilde" tower (also about 300m/980ft).

The construction (Smilde tower) couldn't resist the heat and collapsed, see the video.

http://www.youtube.com/watch?v=VdMLiL4vlHc

Now 80% of the Netherlands can't get national radio over the air (as the Lopik tower is still inoperative because of investigation).

    You cast dispersions, but haven't looked at any of the antenna
systems. Look at just one and see if you any thoughts.
Look at "Hi Z PPL Loop And Flag Arrays.pdf" it's the 5th file down
on the antennas page.

Hi Jeff,
   Why didn't the loop sizes shrink, when the author went from 1296Mhz
to 2400Mhz. First thing I thought about was etching it on a PCB.
But then saw he built the higher freq antenna with the same loop
lengths.
                 Mikek

Hello Michael,

It isn't snake oil, but with many elements, it is difficult to get it
working in practice. Such structures are narrow band and you don't
have a single tuning point to correct something.

If you plan to build an existing antenna, make sure to make a real
good copy of it. Just a good SWR doesn't automatically mean you have
the correct current distribution to get the stated gain.

With kind regards.

Wim

I'm not quite sure what you mean.   However, I have a guess(tm).

>> His curtain quad calculations and NEC2 deck are at:
>> <http://home.comcast.net/~ross_anderson/CurtainQuadFigure11.htm>

If you scroll down to the bottom of the NEC deck, you'll find the line:

```
  FR  0  1  0  0  1332  0       'simulation is at 1332 MHz
```

That's the operating frequency. Change it to 2442 MHz and you have a 2.4GHz antenna.

The element dimensions in the NEC deck are in wavelengths. This makes it very easy to use a design on different frequency. In order to obtain construction lengths, simply multiply each element length by the free space wavelegth. For 2.4GHz, that's about 12.5cm.

. .. and it looks like he has a serious hard-on for anybody who's a ham or an engineer or both. I applied to join the group, stating those things about myself and saying I had a lifelong interest in improving radio reception. I don't recall that I said anything else.

Here's what happened next (quoting from yahoo's email to me):

Hello,

Your request to join the thedallasfiles group was not approved. The moderator of each Yahoo! group chooses whether to restrict membership in the group. Moderators who choose to restrict membership also choose whom to admit.

Please note that this decision is final and that Yahoo! Groups does not control group membership.
< remaining form-letter chatter snipped >

Doesn't make a whole lot of sense

to me. I planned to be an asset in his group. Anybody
have the same experience or am I special? ;-)

   Ah.. I'm still confused, For the 1296 antenna he used 2" x 3" fence
material and then the same 2" x 3" for the 2.4Ghz antenna except for
wire diameter.
                 Mikek

That's just the reflector material. Quoting from the above URL:
  "The antenna is constructed from 3 inch by 2 inch galvanized
  welded wire fence. Wire radius is 0.039 inch."

The reflector is not sensitive to the wire spacing as long as it's
sufficiently small. You could use chicken wire, wire mesh, metal
window bug screening, a barbeque grill, etc for the reflector. I used
some gastly 1/4" galvanized wire mesh, covered with aluminum foil.
For 1.2Ghz, his relfector is 28x21 inches. For 2.4Ghz:
<http://home.comcast.net/~ross_anderson/2400MHzAntenna.htm>
he didn't mention the size of the reflector, but it would half the
size of the 1.2GHz reflector.

That's funny, but note the next post, "a quick followup," which I wrote and sent during the lag time before yours appeared.

Special, ordinary ... whatever I am; apparently I can join, after all.

This all seems odd to me.
I had no problem getting admitted, he works with several hams regarding
his antenna systems, so it's not about hams.

I think he has some great research using single, dual and quad phased
Flag or Delta antennas. There's also info on building a circuit for
adjustable phasing of two antennas.

So get another email address and just say you have an interest in
improving your AM radio reception.

Copied and pasted from the Curtain site.

13 element Curtain Quad for 1296MHz described

The material list is as follows:

----

3 inch by 2 inch welded wire fence (from Orchard Supply Hardware).
The wire radius is about 0.039 inch, which is what #14 steel wire is
when galvanized.---Foam insulation 2 inch thick

And then the parts list for the 2.4Ghz antenna

....

3 inch by 2 inch welded wire fence (bought locally from Orchard Supply
Hardware). The wire radius is about 0.031 inch, which is what #16 steel
wire is when galvanized.--- Foam insulation 1 inch thick

....

As you can see the loops lengths are the same, 3 inch by 2 inch
size. The wire radius is reduced from 0.039" to 0.31" for the 2.4Ghz
antenna, and the reflector distance is doubled.

I can't tell if maybe he has cut out wires on the 1296 antenna
to double the area, no that would quadruple the area.

This will be my last attempt to understand, so give it one more shot
to inform me. :-)
                     Thanks, Mikek

But, yet, I got turned down again, even though I fully complied with his directions. The problem is that I politely added my opinion that his methodology for rejecting his group's applicants had a flaw in my case. (He had earlier explained some of it to me in a thoughtful and candid private email.) Obviously, I should have kept my opinion to myself. I live and learn.

He responded to me with a curt one-line private email saying that the flaw was in _my logic_. From that, coupled with his third rejection two minutes later, I conclude that the mere mention of anything negative is an instant deal-breaker. He had earlier described trouble he'd had in his group with people he termed "bad boys." It's much easier to be dubbed one of his "bad boys" than I would have guessed. Wow!

Yes, I could try to trick him with another email address; however, since I'm not welcome at his front door, why risk the humiliation if he catches me prying open a back window? I'm already somewhat annoyed at myself for this missed opportunity. Why make it worse?

OK, so the final score is Dallas 3, Me 0. Game over. *sigh*

Thanks for the info, Sal. I had entertained the thought of signing up.
Apparently, it's not worth it.

John - KD5YI

Well it is worth it, if you have an interest in broadcast band phased
receiving antennas. Once your in, you can download the pdf files or just
look them over to your hearts content.
I was just hoping for someone else to talk nulling antennas with.
oh well,
John if you send me a private email, I'll send a sample or two
of what's on the site.

```
         Thanks,  Mikek
```

I appreciate the offer, MikeK, but I'm not interested in material where
the keeper is so hard-nosed.

Thanks anyway.

I wouldn't say that. I don't know! Give it a try.

Academically, he certainly has credentials. I easily discovered article references showing he holds a PhD in Mathematics. He's a current university professor and a widely regarded antenna expert.

I think he just doesn't tolerate people who cross him. I can't, in good conscience, condemn him outright for that. Maybe he's just over his lifetime toleration for the behavior of smart-ass 18-year-olds (and anybody else that doesn't fly right).

Sal

Nope, that's not the "loops" or what I call the "spider web". The
fence wire is the meterials for the reflector, not the spider web. No
clue why the wire gauge changed. I used both insulating foam board
and 1/4" galvanized wire cloth.

Incidentally, I was wrong about the NEC deck being in wavelengths.
It's in inches, which is not my favorite way of doing it. I have a
version somewhere where I converted it to wavelengths. Digging...

All I could find is the original 1.2Ghz desk. See:
<http://802.11junk.com/jeffl/antennas/Curtain-Quad-13/index.html>

>   I can't tell if maybe he has cut out wires on the 1296 antenna
>to double the area, no that would quadruple the area.

Yep. Double the frequency and all the dimensions are half. That
creates an antenna with 1/4th the area.

>This will be my last attempt to understand, so give it one more shot
>to inform me. :-)

Incidentally, when I built the 2.4Ghz version, it resonated too low in
frequency. I eventually discovered that my bending fixture (graph
paper, plywood board, and plenty of 10 penny nails) resulted in a bit
too wide a bend at the corners, thus elongating the elements. The 13

```
element calculated gain was 16dBi.  My measured gain was about 14dBi
which isn't too bad considering my marginal method of measurement.
Photos when I find where I buried the antenna.

It is more of a BLOG than a Forum. I have not found anything that
especially interests me yet. That does not keep me from checking in
from time to time.

I doubt there are few of us that don't seem a bit weird to some
people. My guess is that he wants to share his work without having to
give up time to those who just contribute to the noise level.

Now you see why I will not have anything to do with a
"group" that you must sign up for. Never have, and never will.
Many of them seem to like to play their silly games, have
control over what is posted, banish the hecklers, etc..
No way to live as far as I'm concerned.
And I don't need him to learn about phased broadcast
band antennas. It's not like he invented them or anything.
He's just tinkering with a few, and I presume posting his
results to the few that he deems worthy..   :/

Almost sounds like arson if fire pops up in two of them
hours apart.
Kind of reminds me of one we had fall several years
ago. But it was taller than that one. About a 2000
foot job, and it killed seven people that were assembling
it at the time.
Here is some old video of it.. This is just a few miles
from my house. I can see them from here if no trees are
in the way. There are several tall BC towers out at that
senior road site.

Sorry Jeff, I need to try again,
Either I'm doing a very poor job of explaining my lack of understanding
or maybe we are looking at two different pages.
If you look here;
http://home.comcast.net/~ross_anderson/2400MHzAntenna.htm
you will see the FENCE is used as the ANTENNA ELEMENTS and aluminum foil
used as the reflector.
But the fence loops >seem< to me to be the same size for both 1296Mhz
and 2.4Ghz antenna.
Mikek

Much as I enjoy conspiracy theories, the current guess is overheated
cables:
<http://sw-radio.blogspot.com/2011/07/overheated-cables-thought-to-have.html>

More tower wires, most of which were caused by workmen using a cutting
torch on the monopole, and igniting the polyethylene insulation in the
coax cables:
<http://802.11junk.com/jeffl/SCCARC-talk-2010-06-18/Burning-Towers.htm>

Hello Mark,

I thought the same, but according to the current info (speculation?),
it wasn't arson.

At this moment there is no info on the Dutch Safety Board's website
(www.onderzoeksraad.nl), so we have to wait for real info.

The Senior Road FM/TV tower;
Really bad that "some" miscalculation resulted in overstress in a
U-bolt with such horrible end-result. There is lots of info on the web
regarding this accident.

Thank you for sharing your info,

Wim
PA3DJS
www.tetech.nl
Please remove abc first in case of PM

PS: I spent lots of hours with FS98 (mostly IFR and misusing jets as gliders).

Yup. Such groups are very orderly but sometimes
"free-swinging" is more productive.

I concur with your observation, Mikek. It may be that Jeff has looked
only at the first listed reflector which was identical to the antenna
itself.

Both the 1296 and 2.4gHz antennas use the same fencing material.

Nope, my mistake. Brain damage and assumption on my part.

<http://home.comcast.net/~ross_anderson/CurtainQuadFigure11.htm>
<http://home.comcast.net/~ross_anderson/2400MHzAntenna.htm>

I didn't use the recommended fencing material. Instead, I made mine from some #16 awg solid copper wire, soldering the junctions together. When I built the 2.4GHz version, I scaled it from the 1.2GHz dimension, resulting in NOT using the 2x3" fencing material. I then built it without looking at the original article again. I'll dig deeper and see if I can find the 2.4GHz antenna and design data.

That brings me back to the original question, which is how can both antennas be made from the same 2x3" fencing material. I'm not sure what's happening because the drawings are not fully dimensioned. I also just noticed that the grid paper shown do not match the dimensions listed in the NEC deck. Logic (and guesswork) would suggest that if the 2x3" mesh was used for 2.4GHz, then every other wire could be used on 1.2GHz, forming a 2x6" mesh. However, I can't tell from the dimensioning. I'll try to transplant the dimensions to a common drawing, and see if it can be decoded.

Gone to do some chain sawing. More if I survive.

> band antennas.

I want to learn, do you have any sites with good broadcast band antennas.

It's not like he invented them or anything.

He's not claiming invention, but he has made a nice contribution to the hobby.

> He's just tinkering with a few, and I presume posting his
> results to the few that he deems worthy..   :/
>

Tinkering seems a little insincere, I'm sure he ha smany hundreds of hours into his research.

Please post any websites you have regarding broadcast band antennas.
I have not found much other than resonant loops and beverages.

Who says it's all great information? Some may be. Some
may not. I'm not going to jump through hoops to find out
one way or the other.

>
> > And I don't need him to learn about phased broadcast

Well...Google is your friend.. He's not the only one to run
those ya know..
http://search.yahoo.com/search;_ylt=AuKAbH0VcbrAoAiR3zgQWm6bvZx4?
p=quad+delta+flag+array&toggle=1&cop=mss&ei=UTF-8&fr=yfp-t-701

I'm sure I can gather some usable info without having
to jump through a hoop.

>

No problem with that. But I'm not going to be a
spectator if I have to jump through hoops, be censored,
moderated, vetted, etc, ad nausium..   :+

He probably does. But what does that have to do with me?

>
> Please post any websites you have regarding broadcast band antennas.
> I have not found much other than resonant loops and beverages.
>                      Mikek

Already gave one example above. I think W8JI was using
some sort of steerable verticals, and he might have some
info on his site. As I recall, they were pretty short,
and maybe not even resonant, but I don't recall how he
was steering them.
There is tons of stuff out there.. And there is always
that source many seem to ignore these days. Books.

Myself, I happen to like loops.. I'm more interested in
a good null, than I am a really directional pattern like a
flashlight. I don't have the room to run a decent beverage
here. I can do it at my dirt patch out in the sticks, but
I've never got around to stringing the wire up.
I intend to do it one of these days just to give em a try.
Anyway, I've been fairly satisfied just using the various
loops I have for general AM-BC use.
If I decide to build something a tad more exotic, I'll
dig up the info, and I won't be jumping through hoops to
get it. Plenty of other flag array users out there.
No need for me to bother Dallas about it.

For receive only, and moderate bandwidth, then digitizing the multiple antennas and doing the phasing in software is probably the easiest approach. Essentially infinite variability, you get "true time delay" as opposed to phasing (the latter is inherently narrower band, although for AM BC band, it might not make any difference.. 150 ft is a tiny fraction of a wavelength).

> reduce complexity.
>
> How many antenna elements? At least three, I would suspect. From there on it is a matter of how well you can resolve the various delay angles for steering a broad beam angle. Increase the number of elements and the beam angle gets progressively tighter. You don't say how much directionality you want, but it will be intimately correlated with this count.

In general, you can place N-1 nulls with an array of N antennas. Broad nulls (in angular extent) are done by stacking multiple narrow nulls. For AM BC band (which is like 160m ham band), gain isn't a big deal, you'll be interference and atmospheric noise limited.

>
> The delay lines will have to be tolerant of mutual coupling - better yet, they should not perturb the existing mutual coupling at all. Good isolation amplifiers between each element and its delay line before going to a summing amplifier would seem a solution. Tracking between delay lines will affect beam width. More elements will require tighter tracking.

The usual scheme is to use a lossy short untuned antenna and a FET pre-amp. There are several nice designs out there, or you can buy them off the shelf.
http://www.amrad.org/projects/lf/actant/ is an example

> In the end, they all comprise the same fundamentals. If you cannot support a symmetrical design, that is your primary limiting factor. If you can digitize the delay lines, then symmetry can be synthesized and the antennas can be placed physically anywhere limited only by the resolution of digital sampling rate.

And the dynamic range of the amplifier/digitizer.

Interesting, out of the first 11 hits 9 of them are antennas from Dallas's site, One is a site about 160 meter antennas and one is about math (square arrays).

> I'm sure I can gather some usable info without having
> to jump through a hoop.

I still want to learn, do you have a specific site with a good broadcast band receiving antenna. Preferably with a null I can rotate and that will fit in 150 ft.
Thanks, Mikek

I have a Heath HM-2102 VHF SWR power meter 50-160 MHz
0-25 and 0-250 watts. Excellent condition.

I'm *asking* $40 plus shipping.

It can be viewed at:

http://home.comcast.net/~hsknoll/site/?/photos/
&PHPSESSID=29ec62ea0bf1fe4d25e318b011cf0bbf

or

http://tinyurl.com/yktwxpz   click on photo to enlarge it.

Ya shoulda just kept your mouth shut rather than call him out on his "flaw"
telling him you you don't respect him and just have to have the last word.
His not allowing members posts should have given you a clue he is ultra
anal. The outcome was predictable. Ya shoulda kept your mouth shut.

Oh yeah, I got in too.

Here are 2 good ones that I frequent and their email addresses.
1) SkyWires in yahoogroups  <SkyWires@yahoogroups.com>

2) Loopantennas in yahoogroups  <loopantennas@yahoogroups.com>

You can also do a search from the Yahoogroups find a group pages for "Loop
antennas" "BCB" "AM radio" & "MW" to name a few.

how deep a null, how narrow/wide?

One of the noise canceling boxes with two antennas will do quite well.
Timewave ANC-4 is one possibility
MFJ 1026 is another.
DX engineering NCC-1

For BC band, almost any antenna will work.

If you want physically small you could use any of the active antennas..
You could use a MFJ1020C,1022,1024, Ameco TPA, DX Engineering ARAV3-1P, etc.
The MFJ 1026 canceller includes an antenna.

A whole bunch of kits out there..
Ramsey AA7B, the Amrad antenna, ..

If you want to get more sophisticated, some sort of software receiver
might be better approach (you could use more than 2 antennas, for
instance). There's not much off the shelf, but if you're ambitious you
might look at K1LT's array using softrock receivers.http://www.k1lt.com/

In BCB SWLing you want the null(s) deep (and steerable)
to kill the strong, unwanted station.

Hi,

Just getting back on the air after many years of silence and I find myself struggling over the choice of antennas. I need something that I can easily raise and lower (get out of site due to CCR rules) so we're talking about a compromise. I do have room for a couple of radials (max 30 ft) as long as they can buried in the ground 180 degrees apart (not ideal). The antenna will have to be installed within about 4 feet from the side of my house. I was hoping to find a self supporting vertical betwwen 30 and 40 ft hight that could pivit at the base (might need to purchase that separately) so it can be laid down flat on the ground next to the house when not in use. I plan on purchasing an auto tuner if necessary. The vertical can have no physical radials on the antenna itself.

And by the way, I live in the hills above Henderson, NV so the quality of the ground isn't good; lots of rock and hard clay with poor drainage.

Purchase price up to $400.00 OK. Any ideas of what might work in my situation?

Many thanks in advance!

This characteristic demands the SAME considerations as required for a sharp beam of high directionality.

If we were to select the antenna that matches your quoted specs above, it would be called the Cardiod (example available in EZNEC). Problem there is the 30dB null isn't steerable (not enough elements). And it is large (too large for the back yard):
1. Too tall for most to build.
2. Elements too far apart (out of necessity for, dare I say it? Phasing).

As it is designed as a transmit antenna, too tall is quickly dismissed. You can use as short of one as proves useful.

The first element, now being shorter, also allows us to add any number of shorter elements in an array around (or mixed in with) the first. This brings steerability. The more elements, the better angle resolution and null depth control.

You can pull the additional elements (if only one more to build a proof of concept Cardiod) closer to the first (dismissing the large spacing objection), and introduce the necessary time/phase control through:
1. cabling;
2. analog delay circuits;
3. digital delay circuits.

Moving to a digital solution controls all variables.

If none of this is covered in the "Dallas Files," it would be best to leave them in the File Cabinet. Jim has provided adequate links to fill in the gaps and no one was injured in the process of obtaining the information.

Hi Jay,

Google for "Sleeve Dipole" (a vertical) which consists of staged tubing, the upper element insulated from the lower. Do not connect the lower element to ground. Thread the driveline coax up inside the lower element and connect the shield to the top inside of the lower element. Connect the coax inner lead to the bottom of the upper element.

As I said, google for images as this description may frustrate you.

Invest the rest of your money (after buying sufficient quantity of tubing) in your tuner. You may still have a lot left over.

Some thoughts on the subject...

If you are going to have an auto tuner, the antenna itself need not be anything more than a piece of tubing.

I have a 34 ft piece of tubing with a SGC-237 and that tuned 160 (kind of marginally) through 10 with no problem.

I added a relay controlled loading coil to switch in for 160/80 and now it tunes 80 faster and 160 no problem.

If your main interest is the lower bands, just make the tubing as long as you can get away with and let the auto tuner deal with it.

If it is next to the house, drive in as much ground rod as you can and use a garden drip system along with some flowers or whatnot around the base of it.

Whatever radials you can install are better than nothing.

Actually, no.
You can form a deep null with a much simpler antenna system than for
high directionality.

All you need is to "cancel" the signal from the undesired direction.

If you had two verticals spaced some distance apart, fed by equal length transmission lines, and one is polarity reversed, you get a fairly sharp null on the line perpendicular to the line between the antennas.
(e.g. a signal coming from broadside will exactly cancel in the combining)

A loopstick antenna on a ferrite core or a multiturn loop, as popular in direction finding, is another example with a fairly sharp null.

Now.. if you want one null, and one null only, that gets a bit trickier in a small space. I don't know that you can do it with only two elements (haven't thought about it much).

And if you want to steer the null.

One traditional approach in direction finding is to use a goniometer or an adcock array.

>

that's the "one null and one null only" problem.

Pivoting is easy. You can buy a nifty thing from a variety of suppliers, or you can use a couple pieces of 2x4 and a gate hinge.

Or, if you're stronger.. you can use the removable tetherball pole approach: a pipe in the ground as a socket, into which you plug the antenna pole.

A gate hinge with a removable pin (a standard door hinge works, too) is nice, because then you can actually disconnect the antenna and carry it away if you like.

You could probably adapt a "swing away" bike rack too.

I plan on purchasing
> an auto tuner if necessary. The vertical can have no physical radials

Autotuner and vertical is a great combination (if the tuner is at the base of the antenna, particularly)

>
> And by the way, I live in the hills above Henderson, NV so the quality
> of the ground isn't good; lots of rock and hard clay with poor
> drainage.

The only problem with "long antenna on high bands" is that the pattern

gets kind of wonky. If you care about this, then something like a 6BTV
trapped vertical might be a better solution. Still with the autotuner
(because it means you don't have to worry about the adjusting the
antenna or it changing as the soil moisture changes, etc.)

>
> Purchase price up to $400.00 OK. Any ideas of what might work in my
> situation?

Galvanized Fence Top Rail is a very cheap pipe available in 20 foot lengths.

EMT (thin wall conduit) is another.

If it's next to something (the house?).. how tall is the house? Can you
just suspend a wire?

That should get you started...

Hence my referenced Cardiod antenna available for modeling with EZNEC.

>A loopstick antenna on a ferrite core or a multiturn loop, as popular in

Mike has explicitly rejected loop solutions.

Something I've already offered (Bellini Tosi Antenna, as well as
Wullenweber) - and has been rejected/ignored. Repetition doesn't seem

to stand much chance against the ongoing cult examination in trying to
parse the entrance qualifications for the Dallas Files.

Which loops (as in recurse, not a pun) us back to the top.

Hi James,

Yes, in large degree given my experience with the Gap Eagle. I figure
it would draw more than the usual attention, and become a target for
the covenants, deeds, and restrictions.

One of these for 10m was the first HF antenna I ever built. I wish I had known then about decoupling the feed line, as I never could get repeatable VSWR data, possibly due to common mode current. Maybe I'll rebuild it and try again with a suitable choke.

I read about the sleeve dipole before I built it and I will pass on a caution: The end where the cable comes out is a high voltage point (expected for the ends of dipoles); higher powers may punch through the coax outer jacket to the coax shield. I use a piece of PVC plumbing pipe as additional separation inside the lower element and never had an issue.

"Sal"

Happy building.

The antenna would be about 4 feet away from the house. The house is 20
ft high at the peak of the roof (single story). The roof is concrete
tile. I've looked into suspending a wire from a telescopic pole but it
seems like it would be a little cumbersome to raise and lower. I've
looked at suspending a long wire between front and back yard trees but
that is a little more permanent and the HOA could bust me if they saw
it. This is why I'm thinking a vertical would be less visible, easier
to setup and take down, and has a fairly small wind load. I do favor
20 - 10 meter bands so that might be a prob elm for the design I'm
considering. I love the fact that cheap, small diameter pipe can work
as well as a commercial product. Thanks for that info!

Richard - Is there such a thing as a multi-band HF sleeve dipole or is
this more of a VHF/UHF solution?

Jim - You've given me new hope! How significant is the length and
depth of the radials? I probably have about 30 feet each way along the
side of the house. Are you suggesting a drip system around the ground
rod to improve the quality of the ground or for decorative reasons or
both?

How about a flagpole vertical. There have been many write ups about them. I
used to live in Las Vegas by Sam's Town & have seen a few installed & you
won't know its a Ham Ant. Google Flagpole Antenna. Don't forget to put the
flag up...Howard K0ACF

Hi Michael,

Looks like the author went to a lot of trouble - with passion.

There is nothing unreasonable about the design or the results.
However, you should note these designs are highly removed from
ground's proximity which can skew many, finely tuned projects.

You should also note what is typically referred to as the decline on
return for your investment as the design gets bigger. Further, in
actual construction, you rarely obtain the mathematical precision that
is required to enjoy the forecasted results.

Hi Wayne,

Actually, it depends more on the ground, or its proximity. If you can get all the energy into the antenna (hence the tuner and BalUn), then it leaves (the whole point of our hobby). If you have very few radials and you are close to ground, when that energy leaves, a lot of it is absorbed into the ground (not very productive).

Now, the height of this radiator can be something of bad thing for the higher bands. 10M will become deaf because most of the energy is oriented high into the sky, and deep into the ground. True, you "could" force a decent match, but that is only half the story of antennas. The same is probably true for 11M, 12M, down to a fairly good match and operational application for 20M and below to, maybe, 60M.

EZNEC should bear out instructive numbers and graphics to all these observations.

One curiosity about this - the 4:1 BalUns. This sounds like a Hail Mary throw - a sop for the sucker. Do you count yourself among that select population? Why? Because technically they would be UnUns. Further, it is strange to think that a transformation ratio of 4:1 is applicable anywhere, much less everywhere.

73's
Richard Clark, KB7QHC
****
Thanks for the comments Richard. Indeed, the EZNEC model that I looked even created a question of which direction was best for a 4:1 "balun". That would require more examination of the data than I have yet done.

My interest would be in a half sized version of the antenna (or less) for 20m and above. I have a pretty good ground available in the form of a metal patio cover. The no-brainer approach is to use full sized 1/4 wave radiators for various bands. But a simple way of tuning a single radiator for multiple bands is more appealing, since band changes are much simpler.

Very real.  I built the 2.4Ghz version.  It works, but is rather
large.  Unless you have plenty of real estate and tall towers, this is
not an HF antenna.

His curtain quad calculations and NEC2 deck are at:
<http://home.comcast.net/~ross_anderson/CurtainQuadFigure11.htm>

There's also the Sterba Curtain
<http://imageevent.com/holl_ands/notfortv/sterba;jsessionid=ldhsj5x2v1.penguin_s>
Gray-Hoverman
<http://imageevent.com/holl_ands/grayhoverman/hovermantype1>
and other antennas
<http://imageevent.com/holl_ands/chireix/chireixmesnyrefl>
resembling a collection of quads.  As long as you get the phasing
correct, almost any geometry will radiate and have gain.

On 6/28/2011 11:02 AM, Richard Clark wrote:

>
> One curiosity about this - the 4:1 BalUns.

As with many of these "matching devices at the base of a vertical" they're not actually a broadband 4:1 ideal transformer. they tend to have a fair amount of leakage inductance and capacitance, and (by empiricism) they have a design which generally improves the match over a wide band. At low frequencies, where the feedpoint Z is low, the shunting effect of the interwinding C isn't as big, so it acts more like a transformer. At higher frequencies where the feedpoint Z is higher, the interwinding C tends to "bypass" the transformer, so it works less like a transformer, and you see more of the Z of the antenna.

You can fool around with some test data and a lumped model (with lots of parasitics) and come up with some numbers for the parasitics that works out pretty well and combined with some loss in the feedline, makes the typical match at the transmitter end not too bad (within the range of a tuner that can handle, say, 2.5:1 or 3:1, mostly reactive)

It is almost impossible to *design* such a thing from that data. I am quite certain that these things were designed by empiricism. Spreading the windings or squishing them, choosing various winding ratios, etc. until it works "good enough".

The underlying problem is, as you pointed out, that a 43 foot radiator on higher bands has a pattern that is somewhat less than ideal.

A trapped vertical might be a better solution, although mechanically a bit more complex and definitely more "antenna looking"..

There are some very clever lumped networks which will tune multiple bands with a single radiator. They're a lot more complex than a simple L and C, (in general, at least one L and one C per band), and they're not designable by simple paper and pencil techniques (so they don't show up in QST articles or in the handbooks), but with a computer to help, it can be done.

Over a 2:1 frequency range, the pattern issues aren't as big a deal too.. You could pick a radiator that's sort of in between.. it's a bit long for 10m and a bit short for 20m.

Hi Wayne,

The Hail Mary I spoke of also includes:
>>requirement to have a tuner at the driving end of the feedline
Kind of a belt and suspenders solution which in the long run makes
this purchase an expensive option to simply buying staged tubing. In
that respect, the only value added could be a decent mount....

>My interest would be in a half sized version of the antenna (or less) for
>20m and above.

Hmmm, sounds like you are a prospect for my suggestion of staged
tubing.

>I have a pretty good ground available in the form of a metal
>patio cover.

And I would presume this to mean an elevated vertical design - good.

>The no-brainer approach is to use full sized 1/4 wave
>radiators for various bands.

There's no obvious advantage there when you have to use a tuner
anyway. They would be helpful in taming the mismatch, so go ahead.

>But a simple way of tuning a single radiator
>for multiple bands is more appealing, since band changes are much simpler.

Look into the topic of "folded monopoles."

I bet it radiates equally poorly in all directions.

Democrats view George Orwell's novel "1984" as a cautionary tale.

Republicans see the novel as their blueprint.

This is only a test post. I have responded to this particular item
twice, once on Sunday and once yesterday. Neither one showed up.
Nothing in what I said would have been censored for any reason. Odd.
I think it said post was successful. I'm checking that now and will
wait to see if this appears in the group.

"Sal"

Hi Richard,

I note that these were designed at 1296. They would likely be a
practical antenna on that band and ground would not be an issue although
trees may be.

I wonder how hard it would be to make one as a printed circuit board?

Not too long do I wonder. The structure will be exactly as defined
within limits of the board specs.

The only issue is how large PCB stock I can buy.

tom

It's unlikely you will see this, but google groups has been
down since the 25th. It seems to be allowing posts, but it's
not showing any new posts since the 25th.
That's why you are not seeing your posts.

Hi Tom,

If you could generate a graphic with controlled geometry at that
scale, and then etch it, yes, I think it would work quite well.

I will now (most modestly) add my own contributions posted some
decade++ ago (humble, humble) at:
http://www.qsl.net/kb7qhc/antenna/fractal/pg244c/index.htm
for which we may thank the ex-N1IR (who graciously abandoned his
soiled moniker for another to inherit) for the fractal variant to
orthodoxy. Oh woe betides the unknowing innocent for whom this may
all seem irreverent and confusingly impenetrable. (Yes, I am in my
cups. Taking a bow. Grandiloquent sweeping gesture to the audience.)

Moses says,
"Love for The Divine did not register quickly in many minds, but at the Birth of The Son of The Creator, mankind became aware of a Higher Being, the True Existence that there was a Divine. At this time in which you live, there are numerous evidences that many, many, many, many men, women and children do not recognize the True Existence of a Creator and All that surrounds The Creator as Ultimate in Purpose, Cause, Reason and Reality."

REVELATION DELIVERED THROUGH FRANCES M. KLUG ON JANUARY 27,2000 AT 2:30 P.M.

MOSES

"I am Moses. Throughout time, human life has been fully aware of the importance of a moral code of ethics versus an immoral code of ethics. In the beginning of Christianity, The Son of The Father stood upon the earth in the human form, as Example, as Direction, as Hope, so that others would learn about the importance of human actions and human abilities, plus human dignities that were perhaps not just normal, but necessary.

Love for The Divine did not register quickly in many minds, but at the Birth of The Son of The Creator, mankind became aware of a Higher Being, the True Existence that there was a Divine. At this time in which you live, there are numerous evidences that many, many, many, many men, women and children do not recognize the True Existence of a Creator and All that surrounds The Creator as Ultimate in Purpose, Cause, Reason and Reality.

As We Saints try in many ways to enlighten mankind of the importance of purity in the mind, in the body, because of the Soul each one is the custodian of, We find that indifference, based on demonic measures, is always evident, because the enemy causes interference that, to individuals, give excuses to not abide by the Commandments of The Creator.

As The Father down through time, since the beginning of time, has used human life, human lives, to be Example, to be Instructors, and to act morally sound, The Father at this time has given to mankind an additional Gift of Divine Love, Words of Direction that cannot be dismissed as normal or personal to the individual through which They come. I assure you It is strictly Guided, Guarded and Delivered by The Divine, just as it was at another time.

The Gift of life is a Gift not always seen for the greatness it is, but there is hope in it, there are Rules that guide it, and there is definitely a Divine Love instilled in it that no other living matter or thing has.

As I speak to you today, I beseech you, look at what is pure, logical, understandable, and has a Goal to it, and resist what is obviously more pleasing to what would be impure, unkind, unjust, totally different than what you can visualize The Kingdom of God to be. So be it."

You are confusing reflection with wave cancellation (destructive interference). I suggest that you study the separate sections on reflections vs interference in "Optics", by Hecht. Nowhere does any optical textbook indicate that superposition and reflection are the same thing (and they are indeed NOT the same thing).

Superposition/interference applies to two or more waves. Reflection applies to a single wave. When a reflected wave is re-reflected, it is always a single wave event. Take a look at one of the s-parameter equations:

b1 =3D s11(a1) + s12(a2) =3D 0

b1 is the reflected voltage toward the source which is, of course, zero when looking into a Z0-match.

s11(a1) is the forward source wave reflected from the physical impedance discontinuity at the Z0-match point. Note: This is a single reflected component of a single forward wave.

s12(a2) is the part of the reflected wave from the load that is transmitted back through the impedance discontinuity at the Z0-match point. Note: This is a single transmitted component of a single reflected wave.

Reflections are now over and done with. What happens next is superposition/interference, i.e. the phasor addition of the two component reflections. Note: The results of the phasor addition of two component waves is NOT a reflection!!!

The zero result of the addition of those two phasors is associated with destructive interference toward the load. That's what causes the 50 ohm Z0-match, not the component reflections. The redistribution of the destructive interference energy back toward the load is NOT a re-reflection and here's why:

A re-reflection preserves the modulation content of the re-reflected wave which can be proved by TV ghosting experiments. Wave cancellation due to destructive interference does NOT preserve the modulation. In fact, any differences in modulation between the two superposed wave components would wind up incident upon the source.

I could design an expensive device that will do exactly that but it is
a lot easier to just calculate the values using Mathcad.

Oh, Mike, you made a funny!  Having been married for more than forty
years, I'm surprised to learn there is even such a thing as good
marriage advice.

73,
Sal

True, but that ignores what is for me the essence of our hobby,
namely,
"Let's try this and see what happens." We're looking for betterment.

Sometime we make smoke  (Me, twice, so far.)
Sometime we make a pleasing discovery.  (Me, too many times to count.)

I will not be changing to the " ... throw a piece of wire ..." school
of thought,
as my organized (or maybe semi-organized :-) experimental process is
more enjoyable.

I should add I spend more time in QSO than I do playing with the
theory.

Thanks.  I did have the current balun but failed to mention it.  I had
25 Mix 43 beads, Coil Winding Specialist P/N SB-6873-43.  I see now
(my after-the-fact research) that Mix 73 would have been more
effective at 20m.  ("We get too soon old and too late smart.")

I have baluns on all my dipoles, two voltage baluns and two eight-turn
coax cable wound baluns on my home station and a spare eight-turn
balun in my travel box.

I have read that the W2DU balun should be repeated at intervals along
```

the feedline, some wavelength fraction, but I found no confirmation in
ten minutes of searching. Got anything on that?

Yes!

I know I've told this story here before, but ...

My first HF antenna was a 10m vertical sleeve dipole. It was mounted only a few feet above ground. With a tuner,
I matched 15m but not 20m. I knew I needed more metal on at least one element, so I grabbed a clip lead and a hunk of wire and headed outside. Near the antenna, I almost tripped over an extension ladder laying on the ground. This is a sign, I thought. I tossed the wire and dragged the ladder over to the dipole and clipped it onto the lower element.

Back inside, I tuned up nicely on 20m and answered a CQ. Had a nice chat with a fellow in Hawaii; five-by copy both ways.

Some wag in this group suggested "ladder line" might improve the setup. Good one.

Hi John,

Perhaps I might answer by nominating some that are more dependent on ground=
.

The classic case would be a monopole worked against real ground, meaning ha=
ving one terminal of the feed line connected to the dirt in some way.

A centre fed dipole rigged very low to real ground is more depended on grou=
nd than one that is higher.

My experience is that if you don't have the time or resources to install a =
substantial ground system, avoid antennas that depend greatly on that groun=
d system for performance. Driving a short conductive stake, or running a wi=
re along the surface, or running a wire into a body of water does not make =
an effective ground system for these purposes.

I recently had QSO with a field station on 40m at about 500km distance. Ini=
tially he had a half wave dipole lying on the ground, and was somewhat surp=
rised that I could work him with 100W from his tx. He raised the dipole to =
5m (15') and we tried 50mW SSB. He reported that I was essentially noise fr=
ee at that, but I could not reduce power any further.

We prove time and time again that anything "works", but an antenna less dep=
endent on the ground usually gives more consistent performance.

Owen

I think i have finally seen the confusion point. you can not at the same time talk about reflected waves and re-reflected waves and also use s parameters or other steady state reflection parameters or impedances... this means you can not talk about individual reflections from the stub connection point without also analyzing the traveling wave inside the stub, nor can you track and sum up all the reflections using the steady state impedance of the stub as if it were a lumped value. to do so violates the conditions where the s parameters and reflection coefficients are valid, the sinusoidal steady state realm.

John, EM wave reflection is what happens to a single wave. EM wave superposition/interference is what happens between two (or more) waves. They are not the same phenomenon and do NOT obey the same rules of physics. Wave cancellation between two waves is *NOT a reflection* but it does *redistribute* reflected energy back toward the load at the Z0-match point. The destructive interference energy toward the source is redistributed as constructive interference energy toward the load but one can tell from the resulting phase and magnitude that it was NOT a reflection.

A good reference on the differences between wave reflection and wave superposition/interference is "Optics", by Eugene Hecht. The international 4th edition is available in paperback for around $20 from Abebooks.com.

Am trying to design a 3 element tape measure antenna for 2 meters with a 10x10 mm aluminium boom. After calculating the dimensions with Yagicad 6.1 the tapes get cut and mounted.

http://img837.imageshack.us/img837/8209/snc14096a.jpg
(Before cable and hairpin match)

The driven element sits on a slider which allows to adjust

for best F/B ratio over the working frequency span of the antenna.
Normally the F/B degrades quickly when tuning off center.

http://img90.imageshack.us/img90/7112/fbratio.jpg

With the driven element on a slider you can move the peak
to the desired frequency, within a certain range.
About 10 MHz span is possible with such a 2 meter antenna

Measuring with a scalar analyzer and tests with actual radio signals
reveal that YAGICAD does calculate too short elements.
Everything is a few MHz too high in frequency, the gain maximum,
the F/B optimum, the resonant frequency, on the antenna,
when built with the YAGICAD dimensions.

The only parameter I can vary in YAGICAD is the element diameter.
The tape measure is iron, 19 mm. Iron can be selected
in YAGICAD, but that only affects little.

I optimize the design for best F/B ratio, because that is what you
want for a direction finding antenna.

I have to add 4 cm to the passive elements and 8 cm to the driven
dipole to get a working antenna, having selected 0,02 m element
diameter in the YAGICAD program. Entering less diameter
worsens the situation.
The boom adds only 1 or 2 mm to the elements, but the final
dimension results are several centimeters off!
The SWR is excellent with the hairpin calculated by YAGICAD.
At least something that works.

Luckily I have a good test equipment and see live on the screen
what the antenna does when I change elements.
But that YAGICAD is a mysterium to me.
After so many revisions I would expect some more realistic results.

w.

Thanks.

Posts seem now to be showing in bursts, but few (?) close to real
time.
Time to spend money for a more dependable newsreader, I suppose.

I sort of expect they will get it straightened out before
too long. I think they are doing some massive changes. The
search engine, groups, the whole mess..
Supposably July 1 is when the new system is supposed to
be kicked in. Whether GG will be right by then, who knows..
I'm using eternal-september.org right now. It's pretty
good for a free news server.
But believe it or not, I actually prefer google groups.
Some people shake their heads when I say that, but screw
em if they can't take a joke.. :/
To me, the web based reader is faster and less cumbersome
than using the regular news readers.
Fer instance, on the regular reader I have to look at each
post individually. With GG I see all posts in a thread at
once. It's faster..
Also, if I start fresh on the news server, I have to log in
with my user name and password. And then I have to type in
the new groups I want to look at.. What a pain..
Where as GG, as my usual groups are saved with my "profile"
or whatever you want to call it.
I'll think I'll keep both going, but if they get GG back

```
in order, I'll likely revert back to it, and keep the
eternal-september.org as a backup.

Archive-name: radio/ham-radio/moderated/crossposting
Revision: 1.1 2009/04/12 19:42:04
Posting-Frequency: posted monthly
URL: http://www.panix.com/~rram/usenet/rram/index.html

Changes followed by "|".

After a 30-day public discussion and feedback period to gauge reader opinions in March of 2009:

http://groups.google.com/group/rec.radio.amateur.moderated/browse_thread/thread/d7d337db35f23326

the rec.radio.amateur.moderated Moderation Team has decided to consider amending its charter, and permit limited simultaneous crossposting to rec.radio.amateur.moderated and one other unmoderated amateur-radio-related discussion newsgroup. We are currently trying this on a temporary basis (90 days, through early July 2009), and adopt it permanently if successful.

Approved rec.radio.amateur.* newsgroups are those that are currently listed in the latest version of the "List of Big Eight Newsgroups" which is crossposted monthly to news.announce.newgroups, news.groups, and news.lists.misc.

Approved alt.radio.amateur.* and alt.ham-radio.* newsgroups are those that have been created consistent with the suggestions in "So You Want to Create an Alt Newsgroup" at:

  http://www.faqs.org/faqs/alt-creation-guide/

Approved regional hierarchy newsgroups are those that contain either "radio.amateur" or "ham-radio" in their names, including uk.radio.amateur and aus.radio.amateur.misc.

We will make every reasonable effort to keep our list of approved newsgroups up-to-date. In case we have overlooked any, and a submission is rejected in error as a result, the rejected submitter can E-mail us at our administrative contact address (in the signature at the bottom of this article, and the default Reply-To for the rejection message) requesting that it be added, and that the article be approved. We may still choose to reject articles crossposted to any alt.* newsgroup with an inappropriate name, including obscene language, embedded name-calling, or encouragement of unlawful conduct.

Please direct any comments, questions, or criticisms to rec-radio-amateur-moderated-request@panix.com.

Someone said it a long time ago: You can't have your cake and eat it too.

One cannot be using the reflected wave to establish a dynamic virtual short while, at the same time, the virtual short is causing a dynamic re-reflection of the reflected wave.

The virtual impedance is (Vfor+Vref)/(Ifor+Iref) but if that is the impedance doing the re-reflection of that same Vref and Iref, then it cannot also be being used to establish the dynamic virtual impedance, i.e. if a virtual impedance is re-reflecting all of the reflected energy, it will necessarily disappear from existence because there is no longer a Vref and Iref to cause it to exist.

Are there any advantages and/or disadvantages to having a dipole where the legs are at a 90-degree angle instead of straight (i.e., one leg oriented north-south; the other east/west)?

Thanks for the interesting links, Owen.   The 4:1 balun did look unusual to me, and EZNEC didn't help reveal the magic involved. As I mentioned before, I have challenging antenna restrictions (not restrictive covenants), and will look some more at a shorter version for higher frequencies.

It is that it is a voltage balun that is the main issue. The transformation ratio is questionable, but not nearly as clear an issue as being a voltage balun between a coaxial feedline and ground mounted vertical where one terminal of each should be close to the same (~ground) potential.

There is often good argument for a current choke or current balun feeding such an antenna. If there is good argument for a 4:1 transformation ratio, then there is good argument for a 4:1 current balun. I suspect that the changed recommendation to a 4:1 unun is because that can be achieved with a simple reconfiguration of the existing component, a low cost customer support solution.

Seller's are caught between supplying product for which there is demand by the ham buyers, and one that can be explained rationally. One balun seller explained that ham buyers want 4:1 voltage baluns for multiband dipoles because when they replace them with 1:1 current baluns, they have problems with flashovers, and they can't match up on some bands. It is true that voltage baluns can facilitate matching on some extreme loads, at the expense of system efficiency, similar effect to some extent to the subject case.

NEC2 does not model conductors passing into the ground well, so you are unlikely to build a good model.

I toyed with creating a model in NEC4, but figured that those who wouldn't see the folly of the AS/Z5 balun idea would not be informed by NEC models anyway.

> before, I have challenging antenna restrictions (not restrictive
> covenants), and will look some more at a shorter version for higher
> frequencies.

Just because the 4:1 voltage balun seems irrational, that doesn't
dismiss the unloaded vertical, nor benefit of a current balun.

But, if you are primarily interested in higher bands, a shorter vertical
with elevated radials will likely be more efficient and less a cloud
warmer pattern wise.

Owen

I am a newbie in EZNEC (eznec.com) antenna modeling, but I tried it with a known-functional arrangement, a 20m dipole at 30 feet.

When I rotated one leg as you described, the feed point impedance came down from 75 ohms, the resonant freq went up slightly out-of-band and the pattern was nearly circular.

I dropped the antenna to 25 feet and the resonant freq came down into the band and the impedance hit 50 ohms almost on the nose.

For all practical purposes, your change is close to an omni. One issue: It has a fairly high take-off angle at 48 degrees. Some people do not worry about take-off angle, the elevation angle of maximum radiation. This is because the differences are only a few dB. It takes 6 dB to make a one s-unit change, so you're not totally ruining your chances for a QSO if you're down a few.

I've runs lots of dipoles set up like that.
Usually because of the location of the end
supports. They generally work fine, and I imagine

the model is accurate enough for gov work.
It's best not to use angles less than 90 degrees
apart though. As you get the legs closer together
like a V beam you should start to see some cancellation
and a reduction in performance. But even those will
work well enough to operate and probably beat some
lesser antennas. 90 degrees apart works just fine.
It alters the pattern, but it's still efficient
assuming it's fed properly. I always prefer coax
for single band dipoles or dipoles fed in parallel.
No matching required, and you will be hard pressed
to beat the efficiency on most any HF band using
normal line lengths.

```

I've been enjoying several Lazy H antenna I built for 10 meters that are being fed with 450 ohm ladder line back to the tuner. They antennas are performing well. The problem is the external baluns I am using back at the tuner heat up even at 100 watts. These are suppose to be 1.5 kw baluns, but they can't handle the impedance mismatch for full legal limit. I have commercial 1:1 voltage baluns and 4:1 voltage baluns.

I decided to build an air core balun in hopes of saving myself the expense of buying several torrid cores. The problem is none of the plans listed in the Bill Orr handbook or that I have found on the Internet actually work. On my one commercial 4:1 balun if I place a 200 ohms resistor across the leads of the balun I get an SWR reading of about 1.1:1. When I build the air core balun listed in the William Orr handbook I get a 2.5:1 SWR.

Hmm..So I decided to try some 4:1 air core balun designs off of the Internet as well. I found the web page below;

"A 4:1 Air-wound Balun"
http://combotec.com/projects/balun14/balun14.html

I built the balun exactly like the web page described. It does not work. 2.5+ SWR on 10 meters with a 200 ohm resistor plugged up to the terminals. The same 200 ohm resistor shows close to a 1.1 on a ferrite 4:1 balun.

So, the Bill Orr 4:1 air core balun listed in his handbook does not work on 10 meters. Neither does his 1:1 air core balun when tested on 10 meters with a 50 ohm resistor. The 4:1 air core balun listed on the web page above does not work either. I'm getting tired of building air core baluns that don't work.

So....,does anyone have any plans for a 4:1 air core balun for feeding 450 ladder from a tuner that you have actually tested and used that and it shows close to a 1.1:a SWR when presented with a 200 ohm load?

By the way, of the 4 or 5 1:1 commercial baluns I purchased back in the 1990s only one of them actually shows a 1.1:SWR when presented with a 50 ohm load. The others show between a 1.7:1 and 2.1:1 SWR on 10 meters, and that is among several baluns that were all the same model from the same manufacturer. I'd post the brand name, but the paper brand labels wore off years ago. I can tell you it has little brass machined screws and brass holders on the sides of the balun and not the piece of copper wire coming out to the eye hooks. They are enclosed inside the typical white PVC pipe with caps on each end and a coax connector at the bottom.

Therein lies a possible explanation of your problems.

If you view the 4:1 voltage balun as device that can transform any load from say 5+j0 to 5000+j0 (just staying on the X=0 axis) at 1kW (for round numbers), you expected it to handle 15A, and withstand 3000Vpk, over more than a decade freqency range, and to have a maximum loss of say 20W (which is about enough to heat the core in most enclosures to Curie point) or 98% efficient.... and then give a near ideal impedance transformation.

Well, it just doesn't happen that easily... as you now know.

Owen

Hi Owen and thanks for responding,

So how do I go about feeding a Lazy H with ladder line back to the tuner for high power without over heating the balun? The tuner is a Dentron MT-3000a. The built in balun is not balanced at all at 10 meters, and I had to bypass it to get the Lazy H's to work properly. Another ham found the same problem with his Dentron MT-3000a when using ladder line on 10 meters. See K8JS's post on eham.net below for his experience with the Dentron MT-3000a internal balun on 10 meters.
The Lazy H antennas work beautifully at 100 watts, but any more than that and the external baluns begin changing value as they heat up. I have seen a Hy-Power 4:1 balun rated at 5 KW that claims it can handle it, and Palomar has a kit claiming to be able to handle it as well. If possible I would like to build it myself. I get alot more bang out of a good signal report if it is on equipment I restored/repaired, an antenna I built, etc.
I also edthe CQ balun/unun book from hamradio.com. Hopefully it will shed some light on the subject

You are correct. I have also measured gain and F/B and side patterns.
And they match predicted quite well.

One design was a 7.5 wavelength 432 EME antenna which had nice ground
noise performance in real world use. Which is very pattern sensitive.

error that the old-time physicists made was assuming that the aether
was made of ordinary matter instead of exotic quantum particles.

Faraday's aether was made of ions and electrons (like copper). Todays space
is made of rare plasma and dust. The most of old-time physicists need the
exotic aether to explain the light polarization. For Faraday the rare plasma
and its vibrations are enough to explain all phenomena.

p.s. if the separation between the two ports is just the discontinuity
connection 'point' then the voltages must be the same and the currents
are exact opposites only because of the direction convention defined,
there can be no difference measuring on one side of a point to the
other.

a1 is the normalized forward voltage on the 50 ohm feedline from the source. a2 is the normalized reflected voltage on the 291.4 ohm feedline from the load. Those are the two sources associated with the impedance discontinuity inside the black box. a2 could just as easily be from a second generator instead of a reflection.

When the single-port model is used, if the impedance is not an impedor, i.e. if the impedance is virtual, the reflection coefficients are virtual reflection coefficients that do not reflect anything and do not absorb power. I will repeat an earlier assertion:

Since a virtual impedance is result of the superposition of a forward wave and a reflected wave, a virtual impedance cannot re-reflect the reflected wave, i.e. one cannot re-reflect the reflected wave while at the same time the reflected wave is being used to generate an impedance. It has to be one or the other. Otherwise, there is a violation of the conservation of energy principle. RF EM ExH energy cannot be used simultaneously to generate a virtual impedance while at the same time being re-reflected.

If the reflected wave is re-reflected, it must be by an impedance other than the virtual impedance generated by the reflected wave itself. If the reflected wave is being used to generate a virtual impedance, it cannot at the same time be being re-reflected.

On Jun 24, 6:27 am, dave <k1ttt%pstn2....@gtempaccount.com> wrote:

> there can be no difference measuring on one side of a point to the
> other.

The total voltage and total current on both sides of the impedance discontinuity must be equal. But the superposition components do not have to be equal and, in fact, cannot be equal. In the case of the Z0-matched example, the forward voltage on the 50 ohm side is 70.7 volts while the forward voltage on the 291.4 ohm side is 241.4 volts. In order for the total voltage to be the same, the reflected voltage on the 291.4 ohm side, which is 170.7 volts, must be subtracted from the 241.4 volts of forward voltage to yield a total of 70.7 volts. For the Z0-matched example:

Vfwd1 =3D Vfwd2 - Vref2

70.7v =3D 241.4v - 170.7v

Please note that the Z0-match point is at a voltage minimum on the 291.4 ohm feedline. 1/4WL toward the load, the total voltage is 241.4+170.7=3D412.1 volts (in a lossless system).

> Do you actually see any relation between quanta and aether theory?

Looks like you assumed I was making an exclusive assertion when it was actually inclusive. What I was saying is that all the people on the opposite side of the argument from the existence of an aether, i.e. the people who argued that a perfect vacuum is absolute nothingness, have been proved wrong. There is indeed a structure inside a perfect vacuum and "quantum aether" is just as good a name for that structure as any other words. I suggest we convert from "luminiferous aether" to "quantum aether" and be done with it.

Note that EM waves cannot propagate through absolute nothingness. That's why light cannot escape the boundaries of the universe.

The single core does not work properly, see http://vk1od.net/balun/gsc/ .

In fact, I would assert that today, VSWR measurements are almost useless for *antenna adjustment and construction*.. and even for adjusting elements. With modern modeling codes which don't require all sorts of little fiddly "correction factors" (e.g. taper or boom factors) to allow simulating a complex structure with a simpler model, a tape measure would be a better tool.

There's a lot of literature from the 50s-70s and even 80s where antennas are constructed and you adjust the element length by using the trusty GDO. (Yep, I remember helping my grandfather assemble a multiband Yagi of some sort in the early 70s doing it that way..)

But today.. mechanical dimensions and a high fidelity model are the way to go.

Where the VSWR measurement would be useful is in two places:
1) Adjusting a wire antenna length... they're usually interacting with the surroundings, so you have to cut and try, and a VSWR sweep is a good way to get there quickly. Putting up that triband multiwire dipole for Field day tomorrow? The Antenna analyzer is your friend when trying to get all those mutually interacting lengths dialed in.

2) A quick check to see if an antenna system that worked before has "broken" in a big way.

I've participated in Field Day every year since 1993, when I was first licensed. Because I had a big 2m beam, I worked that band aggressively, sometimes making the most QSOs. Unfortunately we lost our hilltop FD site in 2009 and the 2m production "down low" was disappointing in '09 and '10.

This year some youngsters want to work 2m, so I'm moving to HF, 20m being the most promising, I think. With the help of EZNEC (evaluation version), I modeled a promising 20m dipole at 30'. It's almost exactly 75 ohms resistive at the freqs I want to use and I'm going to feed it with RG-6, 0.7 dB/100 feet. My radio has an internal tuner to match the 75-ohm cable, if I need it.

I'll report the results.

meaningless hair splitting. if i put a meter on one side of the stub
connection point i will measure the exact same voltage as on the other
side of the connection point. why don't you guys do something
practical instead of arguing about split hairs and things that can't
be measured?

It can be measured. Why don't you go to another group or thread? Nobody
is forcing you to read this one.

I disagree. There are 100W supplied by the source and 100W consumed by
the load. There are 200W in the 291.4 ohm line. 100W of that is just
"passing through". The other 100W is circulating, that is, stored energy
which was put there by the start-up transient. If it is circulating,
then it must be reflected from each end of the 291.4 ohm line.

Cheers,
John

Let's assume that the 100 watts is just "passing through". It would change from 70.7 volts in the 50 ohm environment to 170.7 volts in the 291.4 ohm environment. The reflected power is 100 watts so the reflected voltage is also 170.7 volts. Those two voltages would have to add together to get the forward voltage. The forward voltage is known to be 241.4 volts. Exactly how do you add two 170.7 volt in-phase waves to get a total of 241.4 volts?

Here is actually what happens. Since the physical power reflection coefficient at the Z0-match point is 0.5, only 50 watts of the source power makes it through the impedance discontinuity. That voltage is 120.7 volts. The same thing applies to the reflected power - only 50 watts is re-reflected by the 0.5 power reflection coefficient. So the re-reflected voltage is also 120.7 volts. Adding those two voltages together yields 241.4 volts which we know is the correct forward voltage.

Now you are going to ask how two 50 watt waves can add up to 200 watts forward power. That's just the nature of constructive interference since power is proportional to voltage squared. If we add two 50 watt waves in phase, we get a 200 watt wave. Where did the extra 100 watts come from? Why, from the 100 watts of destructive interference toward the source that eliminated the reflections toward the source.

That's my attitude toward religion so I don't frequent any religious newsgroups.

That meaningless hair splitting is the answer to the apparent contradiction with which Walt is wrestling.

wow, it takes eznec to model a dipole for field day now?  not that
many years ago i ran a competition at field day... given a hunk of
coax(with one connector installed), a roll of wire, and some random
pieces of rope, cut a 10m dipole, get it up in the air, and make a
contact.  no eznec, a tape measure if you really wanted it, and who
knows what the coax was.

Hello Michael,

Owen's reference explains everything in detail.

If you want a very short answer:
The two-core balun has common mode suppression characteristics. That means when your balanced load isn't balanced in real world, the balun will reduce common mode current in both coaxial line as well as balanced line.

The single-core balun is electrically more like an autotransformer with the coaxial ground on the center-tap. This arrangement does not provide any common mode suppression. So only in case of a perfect balanced load, everything will be fine (with the single-core balun).

Now the longer part
If you still want to go for the single-core solution, you may add a separate common mode choke. For common mode behaviour, the two cores in the two-core balun are in parallel. So the effective common mode impedance will be half that of the CM impedance of a single core.

Regarding the number of turns for the balun; when you need 8 turns on each core for the two-core solution, you can use 4 turns for each branch in case of a single core solution. So if you make the single core balun with coaxial cable, you will have 8 turns of coaxial cable around the core.

Slightly off-topic.
Be aware of the fact the actual input or output voltage determines the heat loss in the ferrite cores. So if the VSWR at the balun is very bad, and the balun is in the voltage maximum, core loss may increase significantly.

With kind regards,

Wim

> try it! =A0you will read the exact same voltage on either side of that
> connection point!

I already told you that only applies to the total voltage and total current. You will NOT read the same forward voltage on either side, you will NOT read the same forward current on either side, you will NOT read the same reflected voltage on either side, and you will NOT read the same reflected current on either side. The total voltage and total current are the results of the superposition of the four component voltages and currents that obey the rules of wave reflection mechanics. Recognizing the interference patterns when two phasor voltages are superposed is the key to understanding exactly what is happening to the energy in the waves. At an impedance discontinuity in a transmission line some distance from any active source, the average destructive interference power in one direction MUST equal the average constructive interference power in the opposite direction in order to avoid a violation of the conservation of energy principle.

So why isn't the forward current flowing into the impedance discontinuity equal to the forward current flowing out of the impedance discontinuity? The answer to that question will solve Walt's apparent contradiction between voltages and powers. Look at the Z0-match again.

source--50 ohm--+--1/2WL Z0>50 ohm--50 ohm load

The total current on the 50 ohm side of point '+' is equal to the total current on the Z0>50 ohm side but the current on the 50 ohm side is a flat traveling wave *constant* current while the current on the Z0>50 ohm side is a standing-wave current maximum, i.e. the total current on the Z0>50 ohm side is a *variable* that changes with a change in the measurement point. A variable current is NOT the same as a constant current.

The total voltage on the 50 ohm side is a flat traveling wave *constant* voltage while the voltage on the Z0>50 ohm side is a standing wave voltage minimum, i.e. the total voltage on the Z0>50 ohm side is a *variable* that changes with a change in the measurement point.

The power on the 50 ohm side is V*I where V and I are constant values. The power on the Z0>50 ohm side is V*I*cos(A) where A is the angle between the current phasor and the voltage phasor and, because of the standing waves, all three parameters vary with location on the feedline.

If the reflections toward the source is eliminated, how is it that it
appears to be 50 ohms at that point rather than 291.4 ohms?

John

You answered your own question - if reflections toward the source are
eliminated in a Z0=3D50 ohm environment, the apparent (virtual)
impedance cannot be anything except 50 ohms. When you look at yourself
in the mirror, your reflected apparent (virtual) distance behind the
mirror is the same as your actual distance from the mirror. The
reflection is NOT where it appears to be, i.e. it is virtual.

You said "Since a virtual impedance is result of the superposition of a
forward
wave and a reflected wave, a virtual impedance cannot re-reflect the
reflected wave, i.e. one cannot re-reflect the reflected wave while at
the same time the reflected wave is being used to generate an
impedance."

But, it does. First, it causes the 50 ohms line (looking into the 291.4
ohms line to see a match due to the reflection. Second, the
re-reflection from that discontinuity is half of what maintains the
circulating energy on the line. The other half is the discontinuity of
the non-virtual load.

That sounds fine as far as it goes.

You might consider a 1:1 current balun, a W2DU style one should suit this a=
pplication fine.

I applaud your efforts to understand the thing using a modelling tool. To s=
ome of us, the inquiring mind and the interest in the technology of radio c=
ommunications is what ham radio is really about. For those not so intereste=
d there are contests!

Your model though contains a guess for ground parameters, and possibly othe=
r site effects not included. You must expect some variation from model, but=
 those variations would not cause very high VSWR on the line, line losses s=
hould be quite acceptable, and an ATU should transform the load it sees to =
that required for rated output from the transmitter with quite acceptable l=
osses.

In my experience, antennas less dependent on ground are more likely to give=
 consistent performance for field operations where you usually cannot affor=
d to be installing significant ground systems.

Well done OM.

Owen

Hi, Owen -

Allow me to jump in here and ask: which antennas are less dependent on ground?

John - KD5YI

but you can't do that! they don't like real measurements, only
arguing about their virtual reflections and the separate currents and
voltages.

when someone gives me a voltmeter i can touch to that connection point and measure the 4 components then we can talk. as far as designing anything i need i can do it without giving those s parameters or your 4 components a second thought. it is very easy to transform and combine the impedances to tell me what the load seen by the transmitter is, or to figure out the needed stub for providing a proper match without all that stuff.

And some of us just throw up a piece of wire and are happy with it.

I need a drink.

Democrats view George Orwell's novel "1984" as a cautionary tale.

Republicans see the novel as their blueprint.

KATN

And we get that higher education in a netnews group? I enjoy this group,
but it's the equivalent to getting marriage advice at a bar. Maybe good,
but just as likely really bad.

Yeah, kinda, but that's all right. I already have four working dipoles up at home, each produced much as Dave describes; 40, 20, 20, 10.

I was seeking optimization and I got it. Example: My TS-870 electronic display lights up five little dots for a 1.5:1 SWR. As installed, the new antenna gave me only three little dots -- most of it probably right at the back of the radio in the transition to 75 ohms. I am very, very pleased with the results.

20m was lit up like a Christmas tree all day and into the night. While operating 100W, I logged a new QSO every two to five minutes. (I'm nobody's idea of a contester.) Surprise -- broke a few pileups.

I oriented the antenna for max toward 060 degrees True, the bulk of North America from San Diego. Putting up three guyed 30-foot poles was quite the adventure but it all worked. No blood loss, one blister. :-)

"Sal"

PS: TS-870 reported an untuned 3:1 SWR on 15m, which the tuner handled easily. Many QSOs on 15m.

Have you tried out rec.radio.amateur.policy? I think it's your kind of
group.

The fun part of antenna modeling, at least for me, is seeing how close
the real thing meets the design. We put up an antenna for FD, an 80
meter cut for the cw portion of the band, and hit it on the first try.

As for folks tuning up rain gutters and wire salvaged from an old
toaster, then making an antenna out of it, that's fun too, but the final
result isn't likely to be optimum.
